Package 'Robyn'

July 21, 2025

Type Package

Title Semi-Automated Marketing Mix Modeling (MMM) from Meta Marketing
Science

Version 3.12.1

Maintainer Bernardo Lares <laresbernardo@gmail.com>

Description Semi-Automated Marketing Mix Modeling (MMM) aiming to reduce human bias by means of ridge regression and evolutionary algorithms, enables actionable decision making providing a budget allocation and diminishing returns curves and allows ground-truth calibration to account for causation.

Depends R (>= 4.0.0)

Imports doParallel, doRNG, dplyr, foreach, ggplot2 (>= 3.4.0),
ggridges, glmnet, jsonlite, lares, lubridate, nloptr, patchwork
(>= 1.3.1), prophet, reticulate, stringr, tidyr

Config/reticulate list(packages = list(list(package = ``nevergrad'',
pip = TRUE)))

adstock_geometric   *Adstocking Transformation (Geometric and Weibull)*

Description

adstock_geometric() for Geometric Adstocking is the classic one-parametric adstock function.

adstock_weibull() for Weibull Adstocking is a two-parametric adstock function that allows changing decay rate over time, as opposed to the fixed decay rate over time as in Geometric adstock. It has two options, the cumulative density function "CDF" or the probability density function "PDF".

Usage

```
adstock_geometric(x, theta)

adstock_weibull(x, shape, scale, windlen = length(x), type = "pdf")

transform_adstock(
```

```
    x,
    adstock,
    theta = NULL,
    shape = NULL,
    scale = NULL,
    windlen = length(x)
)

plot_adstock(plot = TRUE)
```

Arguments

x	A numeric vector.
theta	Numeric. Theta is the only parameter on Geometric Adstocking and means fixed decay rate. Assuming TV spend on day 1 is 100€ and theta = 0.7, then day 2 has 100 x 0.7 = 70€ worth of effect carried-over from day 1, day 3 has 70 x 0.7 = 49€ from day 2 etc. Rule-of-thumb for common media genre: TV c(0.3, 0.8), OOH/Print/ Radio c(0.1, 0.4), digital c(0, 0.3).
shape, scale	Numeric. Check "Details" section for more details.
windlen	Integer. Length of modelling window. By default, same length as x.
type	Character. Accepts "CDF" or "PDF". CDF, or cumulative density function of the Weibull function allows changing decay rate over time in both C and S shape, while the peak value will always stay at the first period, meaning no lagged effect. PDF, or the probability density function, enables peak value occurring after the first period when shape >=1, allowing lagged effect.
adstock	Character. One of: "geometric", "weibull_cdf", "weibull_pdf".
plot	Boolean. Do you wish to return the plot?

Details

Weibull's CDF (Cumulative Distribution Function) has two parameters, shape & scale, and has flexible decay rate, compared to Geometric adstock with fixed decay rate. The shape parameter controls the shape of the decay curve. Recommended bound is c(0.0001, 2). The larger the shape, the more S-shape. The smaller, the more L-shape. Scale controls the inflexion point of the decay curve. We recommend very conservative bounce of c(0, 0.1), because scale increases the adstock half-life greatly.

Weibull's PDF (Probability Density Function) also shape & scale as parameter and also has flexible decay rate as Weibull CDF. The difference is that Weibull PDF offers lagged effect. When shape > 2, the curve peaks after x = 0 and has NULL slope at x = 0, enabling lagged effect and sharper increase and decrease of adstock, while the scale parameter indicates the limit of the relative position of the peak at x axis; when 1 < shape < 2, the curve peaks after x = 0 and has infinite positive slope at x = 0, enabling lagged effect and slower increase and decrease of adstock, while scale has the same effect as above; when shape = 1, the curve peaks at x = 0 and reduces to exponential decay, while scale controls the inflexion point; when 0 < shape < 1, the curve peaks at x = 0 and has increasing decay, while scale controls the inflexion point. When all possible shapes are relevant, we recommend c(0.0001, 10) as bounds for shape; when only strong lagged effect is of interest, we recommend c(2.0001, 10) as bound for shape. In all

cases, we recommend conservative bound of c(0, 0.1) for scale. Due to the great flexibility of Weibull PDF, meaning more freedom in hyperparameter spaces for Nevergrad to explore, it also requires larger iterations to converge.

Run `plot_adstock()` to see the difference visually.

Value

Numeric values. Transformed values.

See Also

Other Transformations: `saturation_hill()`, `transformations`

Examples

```
adstock_geometric(rep(100, 5), theta = 0.5)
adstock_weibull(rep(100, 5), shape = 0.5, scale = 0.5, type = "cdf")
adstock_weibull(rep(100, 5), shape = 0.5, scale = 0.5, type = "pdf")
```

---

df_curve_reach_freq   *Robyn Dataset: Reach & frequency simulated dataset*

Description

A simulated cumulated reach and spend dataset by frequency buckets. The headers must be kept as c("spend_cumulated", "response_cumulated", "freq_bucket").

Usage

```
data(df_curve_reach_freq)
```

Format

An object of class `"data.frame"`

spend_cumulated cumulated spend of paid media

response_cumulated cumulated reach of paid media

freq_bucket Frequency bucket for cumulated reach

Value

data.frame
Dataframe.

See Also

Other Dataset: `dt_prophet_holidays`, `dt_simulated_weekly`

Examples

```
data(df_curve_reach_freq)
head(df_curve_reach_freq)
```

---

dt_prophet_holidays   *Robyn Dataset: Holidays by Country*

Description

Contains prophet's "new" default holidays by country. When using own holidays, please keep the header c("ds", "holiday", "country", "year").

Usage

```
data(dt_prophet_holidays)
```

Format

An object of class "data.frame"

ds Date

holiday Name of celebrated holiday

country Code for the country (Alpha-2)

year Year of ds

Value

data.frame

Dataframe. Contains prophet's default holidays by country.

See Also

Other Dataset: df_curve_reach_freq, dt_simulated_weekly

Examples

```
data(dt_prophet_holidays)
head(dt_prophet_holidays)
```

---

dt_simulated_weekly   *Robyn Dataset: MMM Demo Data*

Description

Simulated MMM data. Input time series should be daily, weekly or monthly.

Usage

```
data(dt_simulated_weekly)
```

Format

An object of class `"data.frame"`

DATE Date

revenue Daily total revenue

tv_S Television

ooh_S Out of home

... ...

Value

data.frame

Dataframe. Contains simulated dummy dataset to test and run demo.

See Also

Other Dataset: `df_curve_reach_freq`, `dt_prophet_holidays`

Examples

```
data(dt_simulated_weekly)
head(dt_simulated_weekly)
```

---

hyper_limits	*Check hyperparameter limits*

Description

Reference data.frame that shows the upper and lower bounds valid for each hyperparameter.

Usage

```
hyper_limits()
```

Value

Dataframe. Contains upper and lower bounds for each hyperparameter.

Examples

```
hyper_limits()
```

---

hyper_names	*Get correct hyperparameter names*

Description

Output all hyperparameter names and help specifying the list of hyperparameters that is inserted into robyn_inputs(hyperparameters = ...)

Usage

```
hyper_names(adstock, all_media, all_vars = NULL)
```

Arguments

adstock	Character. Default to InputCollect$adstock. Accepts "geometric", "weibull_cdf" or "weibull_pdf"
all_media	Character vector. Default to InputCollect$all_media. Includes InputCollect$paid_media_spends and InputCollect$organic_vars.
all_vars	Used to check the penalties inputs, especially for refreshing models.

Value

Character vector. Names of hyper-parameters that should be defined.

Guide to setup hyperparameters

See section "Hyperparameter interpretation & recommendation" in demo https://github.com/facebookexperimental/Robyn/bl

Helper plots

    plot_adstock(TRUE) Get adstock transformation example plot, helping you understand geometric/theta and weibull/shape/scale transformation

    plot_saturation(TRUE) Get saturation curve transformation example plot, helping you understand hill/alpha/gamma transformation

Examples

```
media <- c("facebook_I", "print_S", "tv_S")
hyper_names(adstock = "geometric", all_media = media)

hyperparameters <- list(
  facebook_I_alphas = c(0.5, 3), # example bounds for alpha
  facebook_I_gammas = c(0.3, 1), # example bounds for gamma
  facebook_I_thetas = c(0, 0.3), # example bounds for theta
  print_S_alphas = c(0.5, 3),
  print_S_gammas = c(0.3, 1),
  print_S_thetas = c(0.1, 0.4),
  tv_S_alphas = c(0.5, 3),
  tv_S_gammas = c(0.3, 1),
  tv_S_thetas = c(0.3, 0.8)
)

# Define hyper_names for weibull adstock
hyper_names(adstock = "weibull_pdf", all_media = media)

hyperparameters <- list(
  facebook_I_alphas = c(0.5, 3), # example bounds for alpha
  facebook_I_gammas = c(0.3, 1), # example bounds for gamma
  facebook_I_shapes = c(0.0001, 2), # example bounds for shape
  facebook_I_scales = c(0, 0.1), # example bounds for scale
  print_S_alphas = c(0.5, 3),
  print_S_gammas = c(0.3, 1),
  print_S_shapes = c(0.0001, 2),
  print_S_scales = c(0, 0.1),
  tv_S_alphas = c(0.5, 3),
  tv_S_gammas = c(0.3, 1),
  tv_S_shapes = c(0.0001, 2),
  tv_S_scales = c(0, 0.1)
)
```

---

    prophet_decomp   *Conduct prophet decomposition*

Description

When `prophet_vars` in `robyn_inputs()` is specified, this function decomposes trend, season, holiday and weekday from the dependent variable.

Usage

```
prophet_decomp(
  dt_transform,
  dt_holidays,
  prophet_country,
  prophet_vars,
  prophet_signs,
  factor_vars,
  context_vars,
  organic_vars,
  paid_media_spends,
  paid_media_vars,
  intervalType,
  dayInterval,
  custom_params
)
```

Arguments

`dt_transform`	A data.frame with all model features. Must contain ds column for time variable values and dep_var column for dependent variable values.
`dt_holidays`	data.frame. Raw input holiday data. Load standard Prophet holidays using `data("dt_prophet_holidays")`
`context_vars,` `paid_media_spends,` `intervalType,` `dayInterval,` `prophet_country,` `prophet_vars,` `prophet_signs,` `factor_vars`	As included in `InputCollect`
`organic_vars`	Character vector. Typically newsletter sendings, push-notifications, social media posts etc. Compared to `paid_media_vars` `organic_vars` are often marketing activities without clear spends.
`paid_media_vars`	Character vector. Names of the paid media variables' exposure level metrics (impressions, clicks, GRP etc) other than spend. The values on each of these variables must be numeric. These variables are not being used to train the model but to check relationship and recommend to split media channels into sub-channels (e.g. fb_retargeting, fb_prospecting, etc.) to gain more variance. `paid_media_vars` must have same order and length as `paid_media_spends` respectively and is not required.
`custom_params`	List. Custom parameters passed to `prophet()`

Value

A list containing all prophet decomposition output.

Robyn	*Robyn MMM Project from Meta Marketing Science*

Description

Robyn is an automated Marketing Mix Modeling (MMM) code. It aims to reduce human bias by means of ridge regression and evolutionary algorithms, enables actionable decision making providing a budget allocator and diminishing returns curves and allows ground-truth calibration to account for causation.

robyn_allocator	*Budget Allocator*

Description

robyn_allocator() function returns a new split of media variable spends that maximizes the total media response.

Usage

```
robyn_allocator(
  robyn_object = NULL,
  select_build = 0,
  InputCollect = NULL,
  OutputCollect = NULL,
  select_model = NULL,
  json_file = NULL,
  scenario = "max_response",
  total_budget = NULL,
```

```
    target_value = NULL,
    date_range = "all",
    channel_constr_low = NULL,
    channel_constr_up = NULL,
    channel_constr_multiplier = 3,
    optim_algo = "SLSQP_AUGLAG",
    maxeval = 1e+05,
    constr_mode = "eq",
    keep_zero_coefs = FALSE,
    plots = TRUE,
    plot_folder = NULL,
    plot_folder_sub = NULL,
    export = TRUE,
    quiet = FALSE,
    ui = FALSE,
    ...
)

## S3 method for class 'robyn_allocator'
print(x, ...)

## S3 method for class 'robyn_allocator'
plot(x, ...)
```

Arguments

robyn_object	Character or List. Path of the Robyn.RDS object that contains all previous modeling information or the imported list.
select_build	Integer. Default to the latest model build. select_build = 0 selects the initial model. select_build = 1 selects the first refresh model.
InputCollect	List. Contains all input parameters for the model. Required when robyn_object is not provided.
OutputCollect	List. Containing all model result. Required when robyn_object is not provided.
select_model	Character. A model SolID. When robyn_object is provided, select_model defaults to the already selected SolID. When robyn_object is not provided, select_model must be provided with InputCollect and OutputCollect, and must be one of OutputCollect$allSolutions.
json_file	Character. JSON file to import previously exported inputs or recreate a model. To generate this file, use robyn_write(). If you didn't export your data in the json file as "raw_data", dt_input must be provided; dt_holidays input is optional.
scenario	Character. Accepted options are: "max_response", "target_efficiency". Scenario "max_response" answers the question: "What's the potential revenue/conversions lift with the same (or custom) spend level in date_range and what is the allocation and expected response mix?" Scenario "target_efficiency"

	optimizes ROAS or CPA and answers the question: "What's the potential revenue/conversions lift and spend levels based on a `target_value` for CPA/ROAS and what is the allocation and expected response mix?" Deprecated scenario: `"max_response_expected_spend"`.
total_budget	Numeric. Total marketing budget for all paid channels for the period in `date_range`.
target_value	Numeric. When using the scenario `"target_efficiency"`, target_value is the desired ROAS or CPA with no upper spend limit. Default is set to 80% of initial ROAS or 120% of initial CPA, when `"target_value = NULL"`.
date_range	Character. Date(s) to apply adstocked transformations and pick mean spends per channel. Set one of: "all", "last", or "last_n" (where n is the last N dates available), date (i.e. "2022-03-27"), or date range (i.e. `c("2022-01-01", "2022-12-31")`). Default to "all".
channel_constr_low, channel_constr_up	
	Numeric vectors. The lower and upper bounds for each paid media variable when maximizing total media response. For example, `channel_constr_low = 0.7` means minimum spend of the variable is 70 average, using non-zero spend values, within `date_min` and `date_max` date range. Both constrains must be length 1 (same for all values) OR same length and order as `paid_media_selected`. It's not recommended to 'exaggerate' upper bounds, especially if the new level is way higher than historical level. Lower bound must be >=0.01, and upper bound should be < 5.
channel_constr_multiplier	
	Numeric. Default to 3. For example, if `channel_constr_low` and `channel_constr_up` are 0.8 to 1.2, the range is 0.4. The allocator will also show the optimum solution for a larger constraint range of 0.4 x 3 = 1.2, or 0.4 to 1.6, to show the optimization potential to support allocation interpretation and decision.
optim_algo	Character. Default to `"SLSQP_AUGLAG"`, short for "Sequential Least-Squares Quadratic Programming" and "Augmented Lagrangian". Alternatively, `""MMA_AUGLAG"`, short for "Methods of Moving Asymptotes". More details see the documentation of NLopt here.
maxeval	Integer. The maximum iteration of the global optimization algorithm. Defaults to 100000.
constr_mode	Character. Options are `"eq"` or `"ineq"`, indicating constraints with equality or inequality.
keep_zero_coefs	
	Boolean. By default, zero coefficient (betas) channels will be removed to avoid spending budget were there is no impact.
plots	Boolean. Generate plots?
plot_folder	Character. Path for saving plots and files. Default to `robyn_object` and saves plot in the same directory as `robyn_object`.
plot_folder_sub	
	Character. Sub path for saving plots. Will overwrite the default path with timestamp or, for refresh and allocator, simply overwrite files.
export	Boolean. Export outcomes into local files?
quiet	Boolean. Keep messages off?

ui   Boolean. Save additional outputs for UI usage. List outcome.

...   Additional parameters passed to `robyn_outputs()`.

x   `robyn_allocator()` output.

Value

A list object containing allocator result.

List. Contains optimized allocation results and plots.

Examples

```
## Not run:
# Having InputCollect and OutputCollect results
AllocatorCollect <- robyn_allocator(
  InputCollect = InputCollect,
  OutputCollect = OutputCollect,
  select_model = "1_2_3",
  scenario = "max_response",
  channel_constr_low = 0.7,
  channel_constr_up = c(1.2, 1.5, 1.5, 1.5, 1.5),
  channel_constr_multiplier = 4,
  date_range = "last_26",
  export = FALSE
)
# Print a summary
print(AllocatorCollect)
# Plot the allocator one-pager
plot(AllocatorCollect)

## End(Not run)
```

---

robyn_calibrate   *Robyn Calibration Function - BETA*

Description

`robyn_calibrate()` consumes source of truth or proxy data for saturation or adstock curve estimation. This is an experimental feature and can be used independently from Robyn's main model.

Usage

```
robyn_calibrate(
  df_curve = NULL,
  curve_type = NULL,
  force_shape = NULL,
  hp_bounds = NULL,
  max_trials = 10,
  max_iters = 2500,
```

```
    loss_min_step_rel = 1e-04,
    loss_stop_rel = 0.05,
    burn_in_rel = 0.1,
    sim_n = 30,
    hp_interval = 0.5,
    quiet = FALSE,
    ...
)
```

Arguments

df_curve	data.frame. Requires two columns named spend and response. Recommended sources of truth are Halo R&F or Meta conversion lift.
curve_type	Character. Currently only allows "saturation_reach_hill" and only supports Hill function.
force_shape	Character. Allows c("c", "s") with default NULL that's no shape forcing. It's recommended for offline media to have "c" shape, while for online can be "s" or NULL. Shape forcing only works if hp_bounds is null.
hp_bounds	list. Currently only allows Hill for saturation. Ranges for alpha and gamma are provided as Hill parameters. If NULL, hp_bounds takes on default ranges.
max_trials	integer. Different trials have different starting point and provide diversified sampling paths. Default to 10.
max_iters	integer. Loss is minimized while iteration increases. Default to 2500.
loss_min_step_rel	
	numeric. Default to 0.01 and value is between 0-0.1. 0.01 means the optimisation is considered converged if error minimization is <1 percent of maximal error.
loss_stop_rel	numeric. Default is 0.05 and value is between 0-0.5. 0.05 means 5 percent of the max_iters is used as the length of iterations to calculate the mean error for convergence.
burn_in_rel	numeric. Default to 0.1 and value is between 0.0.5. 0.1 means 10 percent of iterations is used as burn-in period.
sim_n	integer. Number of simulation for plotting fitted curve.
hp_interval	numeric. Default to 0.95 and is between 0.8-1. 0.95 means 2.5 - 97.5 percent percentile are used as parameter range for output.
quiet	Boolean. Keep messages off?
...	Additional parameters passed to robyn_outputs().

Value

List. Class: curve_out. Contains the results of all trials and iterations modeled.

Examples

```
## Not run:
# Dummy input data for Meta spend. This is derived from Halo's reach & frequency data.
# Note that spend and response need to be cumulative metrics.
data("df_curve_reach_freq")

# Using reach saturation from Halo as proxy
curve_out <- robyn_calibrate(
  df_curve = df_curve_reach_freq,
  curve_type = "saturation_reach_hill"
)
# For the simulated reach and frequency dataset, it's recommended to use
# "reach 1+" for gamma lower bound and "reach 10+" for gamma upper bound
facebook_I_gammas <- c(
  curve_out[["curve_collect"]][["reach 1+"]][["hill"]][["gamma_best"]],
  curve_out[["curve_collect"]][["reach 10+"]][["hill"]][["gamma_best"]])
print(facebook_I_gammas)

## End(Not run)
```

---

robyn_clusters   *Clustering to Reduce Number of Models based on ROI and Errors*

Description

robyn_clusters() uses output from robyn_run(), to reduce the number of models and create bootstrapped confidence interval and help the user pick up the best (lowest combined error) of the most different kinds (clusters) of models.

Usage

```
robyn_clusters(
  input,
  dep_var_type,
  cluster_by = "hyperparameters",
  all_media = NULL,
  k = "auto",
  wss_var = 0.06,
  max_clusters = 10,
  limit = 1,
  weights = rep(1, 3),
  dim_red = "PCA",
  quiet = FALSE,
  export = FALSE,
  seed = 123,
  ...
)
```

Arguments

`input`	`robyn_export()`'s output or `pareto_aggregated.csv` results.
`dep_var_type`	Character. For dep_var_type 'revenue', ROI is used for clustering. For conversion', CPA is used for clustering.
`cluster_by`	Character. Any of: "performance" or "hyperparameters".
`all_media`	Character vector. Default to `InputCollect$all_media`. Includes `InputCollect$paid_media_spends` and `InputCollect$organic_vars`.
`k`	Integer. Number of clusters
`wss_var`	Numeric. Used to pick automatic k value, when k is `NULL` based on WSS variance while considering `limit` clusters. Values between (0, 1). Default value could be 0.05 to consider convergence.
`max_clusters`	Integer. Maximum number of clusters.
`limit`	Integer. Top N results per cluster. If kept in "auto", will select k as the cluster in which the WSS variance was less than 5%.
`weights`	Vector, size 3. How much should each error weight? Order: nrmse, decomp.rssd, mape. The highest the value, the closer it will be scaled to origin. Each value will be normalized so they all sum 1.
`dim_red`	Character. Select dimensionality reduction technique. Pass any of: c("PCA", "tSNE", "all", "none").
`quiet`	Boolean. Keep quiet? If not, print messages.
`export`	Export plots into local files?
`seed`	Numeric. Seed for reproducibility
`...`	Additional parameters passed to `lares::clusterKmeans()`.

Value

List. Clustering results as labeled data.frames and plots.

Author(s)

Bernardo Lares (bernardolares@meta.com)

Examples

```
## Not run:
# Having InputCollect and OutputCollect results
cls <- robyn_clusters(
  input = OutputCollect,
  all_media = InputCollect$all_media,
  k = 3, limit = 2,
  weights = c(1, 1, 1.5)
)

## End(Not run)
```

---

robyn_converge   *Check Models Convergence*

Description

robyn_converge() consumes robyn_run() outputs and calculate convergence status and builds convergence plots. Convergence is calculated by default using the following criteria (having kept the default parameters: sd_qtref = 3 and med_lowb = 2):

Criteria #1: Last quantile's standard deviation < first 3 quantiles' mean standard deviation

Criteria #2: Last quantile's absolute median < absolute first quantile's absolute median - 2 * first 3 quantiles' mean standard deviation

Both mentioned criteria have to be satisfied to consider MOO convergence.

Usage

```
robyn_converge(
  OutputModels,
  n_cuts = 20,
  sd_qtref = 3,
  med_lowb = 2,
  nrmse_win = c(0, 0.998),
  ...
)
```

Arguments

OutputModels   List. Output from robyn_run().

n_cuts   Integer. Default to 20 (5% cuts each).

sd_qtref   Integer. Reference quantile of the error convergence rule for standard deviation (Criteria #1). Defaults to 3.

med_lowb   Integer. Lower bound distance of the error convergence rule for median. (Criteria #2). Default to 3.

nrmse_win   Numeric vector. Lower and upper quantiles thresholds to winsorize NRMSE. Set values within [0,1]; default: c(0, 0.998) which is 1/500.

...   Additional parameters

Value

List. Plots and MOO convergence results.

Examples

```
## Not run:
# Having OutputModels results
MOO <- robyn_converge(
  OutputModels,
  n_cuts = 10,
  sd_qtref = 3,
  med_lowb = 3
)

## End(Not run)
```

---

robyn_inputs   *Input Data Check & Transformation*

Description

robyn_inputs() is the function to input all model parameters and check input correctness for the
initial model build. It includes the engineering process results that conducts trend, season, holiday
& weekday decomposition using Facebook's time-series forecasting library prophet and fit a non-
linear model to spend and exposure metrics in case exposure metrics are used in paid_media_vars.

Usage

```
robyn_inputs(
  dt_input = NULL,
  dep_var = NULL,
  dep_var_type = NULL,
  date_var = "auto",
  paid_media_spends = NULL,
  paid_media_vars = NULL,
  paid_media_signs = NULL,
  organic_vars = NULL,
  organic_signs = NULL,
  context_vars = NULL,
  context_signs = NULL,
  factor_vars = NULL,
  dt_holidays = Robyn::dt_prophet_holidays,
  prophet_vars = NULL,
  prophet_signs = NULL,
  prophet_country = NULL,
  adstock = NULL,
  hyperparameters = NULL,
  window_start = NULL,
  window_end = NULL,
  calibration_input = NULL,
  json_file = NULL,
```

```
    InputCollect = NULL,
    ...
  )

## S3 method for class 'robyn_inputs'
print(x, ...)
```

Arguments

dt_input	data.frame. Raw input data. Load simulated dataset using `data("dt_simulated_weekly")`
dep_var	Character. Name of dependent variable. Only one allowed
dep_var_type	Character. Type of dependent variable as "revenue" or "conversion". Will be used to calculate ROI or CPI, respectively. Only one allowed and case sensitive.
date_var	Character. Name of date variable. Daily, weekly and monthly data supported. `date_var` must have format "2020-01-01" (YYY-MM-DD). Default to automatic date detection.
paid_media_spends	
	Character vector. Names of the paid media variables. The values on each of these variables must be numeric. Also, `paid_media_spends` must have same order and length as `paid_media_vars` respectively.
paid_media_vars	
	Character vector. Names of the paid media variables' exposure level metrics (impressions, clicks, GRP etc) other than spend. The values on each of these variables must be numeric. These variables are not being used to train the model but to check relationship and recommend to split media channels into sub-channels (e.g. fb_retargeting, fb_prospecting, etc.) to gain more variance. `paid_media_vars` must have same order and length as `paid_media_spends` respectively and is not required.
paid_media_signs	
	Character vector. Choose any of c("default", "positive", "negative"). Control the signs of coefficients for `paid_media_vars`. Must have same order and same length as `paid_media_vars`. By default, all values are set to 'positive'.
organic_vars	Character vector. Typically newsletter sendings, push-notifications, social media posts etc. Compared to `paid_media_vars` `organic_vars` are often marketing activities without clear spends.
organic_signs	Character vector. Choose any of "default", "positive", "negative". Control the signs of coefficients for `organic_vars` Must have same order and same length as `organic_vars`. By default, all values are set to "positive".
context_vars	Character vector. Typically competitors, price & promotion, temperature, unemployment rate, etc.
context_signs	Character vector. Choose any of c("default", "positive", "negative"). Control the signs of coefficients for context_vars. Must have same order and same length as `context_vars`. By default it's set to 'defualt'.
factor_vars	Character vector. Specify which of the provided variables in organic_vars or context_vars should be forced as a factor.

dt_holidays   data.frame. Raw input holiday data. Load standard Prophet holidays using
                     `data("dt_prophet_holidays")`

prophet_vars   Character vector. Include any of "trend", "season", "weekday", "monthly", "hol-
                     iday" or NULL. Highly recommended to use all for daily data and "trend", "sea-
                     son", "holiday" for weekly and above cadence. Set to NULL to skip prophet's
                     functionality.

prophet_signs   Character vector. Choose any of "default", "positive", "negative". Control the
                     signs of coefficients for `prophet_vars`. Must have same order and same length
                     as `prophet_vars`. By default, all values are set to "default".

prophet_country
                     Character. Only one country allowed. Includes national holidays for all coun-
                     tries, whose list can be found loading `data("dt_prophet_holidays")`.

adstock   Character. Choose any of "geometric", "weibull_cdf", "weibull_pdf". Weibull
                     adstock is a two-parametric function and thus more flexible, but takes longer
                     time than the traditional geometric one-parametric function. CDF, or cumulative
                     density function of the Weibull function allows changing decay rate over time
                     in both C and S shape, while the peak value will always stay at the first period,
                     meaning no lagged effect. PDF, or the probability density function, enables
                     peak value occurring after the first period when shape >=1, allowing lagged
                     effect. Run `plot_adstock()` to see the difference visually. Time estimation:
                     with geometric adstock, 2000 iterations * 5 trials on 8 cores, it takes less than
                     30 minutes. Both Weibull options take up to twice as much time.

hyperparameters
                     List. Contains hyperparameter lower and upper bounds. Names of elements
                     in list must be identical to output of `hyper_names()`. To fix hyperparameter
                     values, provide only one value.

window_start, window_end
                     Character. Set start and end dates of modelling period. Recommended to not
                     start in the first date in dataset to gain adstock effect from previous periods.
                     Also, columns to rows ratio in the input data to be >=10:1, or in other words at
                     least 10 observations to 1 independent variable. This window will determine the
                     date range of the data period within your dataset you will be using to specifically
                     regress the effects of media, organic and context variables on your dependent
                     variable. We recommend using a full `dt_input` dataset with a minimum of 1
                     year of history, as it will be used in full for the model calculation of trend, sea-
                     sonality and holidays effects. Whereas the window period will determine how
                     much of the full data set will be used for media, organic and context variables.

calibration_input
                     data.frame. Optional. Provide experimental results to calibrate. Your input
                     should include the following values for each experiment: channel, liftStartDate,
                     liftEndDate, liftAbs, spend, confidence, metric. You can calibrate any spend or
                     organic variable with a well designed experiment. You can also use experimental
                     results from multiple channels; to do so, provide concatenated channel value, i.e.
                     "channel_A+channel_B". Check "Guide for calibration source" section.

json_file   Character. JSON file to import previously exported inputs or recreate a model.
                     To generate this file, use `robyn_write()`. If you didn't export your data in

the json file as "raw_data", `dt_input` must be provided; `dt_holidays` input is optional.

InputCollect   Default to NULL. `robyn_inputs`'s output when `hyperparameters` are not yet set.

...   Additional parameters passed to `prophet` functions.

x   `robyn_inputs()` output.

Value

List. Contains all input parameters and modified results using Robyn:::robyn_engineering(). This list is ready to be used on other functions like robyn_run() and print(). Class: robyn_inputs.

Guide for calibration source

1. We strongly recommend to use experimental and causal results that are considered ground truth to calibrate MMM. Usual experiment types are people-based (e.g. Facebook conversion lift) and geo-based (e.g. Facebook GeoLift).

2. Currently, Robyn only accepts point-estimate as calibration input. For example, if 10k$ spend is tested against a hold-out for channel A, then input the incremental return as point-estimate as the example below.

3. The point-estimate has to always match the spend in the variable. For example, if channel A usually has 100k$ weekly spend and the experimental HO is 70

Examples

```
# Using dummy simulated data
InputCollect <- robyn_inputs(
  dt_input = Robyn::dt_simulated_weekly,
  dt_holidays = Robyn::dt_prophet_holidays,
  date_var = "DATE",
  dep_var = "revenue",
  dep_var_type = "revenue",
  prophet_vars = c("trend", "season", "holiday"),
  prophet_country = "DE",
  context_vars = c("competitor_sales_B", "events"),
  paid_media_spends = c("tv_S", "ooh_S", "print_S", "facebook_S", "search_S"),
  paid_media_vars = c("tv_S", "ooh_S", "print_S", "facebook_I", "search_clicks_P"),
  organic_vars = "newsletter",
  factor_vars = "events",
  window_start = "2016-11-23",
  window_end = "2018-08-22",
  adstock = "geometric",
  # To be defined separately
  hyperparameters = NULL,
  calibration_input = NULL
)
print(InputCollect)
```

---

robyn_mmm   *Core MMM Function*

Description

robyn_mmm() function activates Nevergrad to generate samples of hyperparameters, conducts media transformation within each loop, fits the Ridge regression, calibrates the model optionally, decomposes responses and collects the result. It's an inner function within robyn_run().

Usage

```
robyn_mmm(
  InputCollect,
  hyper_collect,
  iterations,
  cores,
  nevergrad_algo,
  intercept = TRUE,
  intercept_sign,
  ts_validation = TRUE,
  add_penalty_factor = FALSE,
  objective_weights = NULL,
  dt_hyper_fixed = NULL,
  rssd_zero_penalty = TRUE,
  refresh = FALSE,
  trial = 1L,
  seed = 123L,
  quiet = FALSE,
  ...
)

model_decomp(inputs = list())
```

Arguments

InputCollect	List. Contains all input parameters for the model. Required when robyn_object is not provided.
hyper_collect	List. Containing hyperparameter bounds. Defaults to InputCollect$hyperparameters.
iterations	Integer. Number of iterations to run.
cores	Integer. Default to parallel::detectCores() - 1 (all cores except one). Set to 1 if you want to turn parallel computing off.
nevergrad_algo	Character. Default to "TwoPointsDE". Options are c("DE","TwoPointsDE", "OnePlusOne", "DoubleFastGADiscreteOnePlusOne","DiscreteOnePlusOne", "PortfolioDiscreteOnePlusOne", "NaiveTBPSA","cGA", "RandomSearch").
intercept	Boolean. Should intercept(s) be fitted (default=TRUE) or set to zero (FALSE).

intercept_sign   Character. Choose one of "non_negative" (default) or "unconstrained". By default, if intercept is negative, Robyn will drop intercept and refit the model. Consider changing intercept_sign to "unconstrained" when there are `context_vars` with large positive values.

ts_validation   Boolean. When set to `TRUE`, Robyn will split data by test, train, and validation partitions to validate the time series. By default the "train_size" range is set to `c(0.5, 0.8)`, but it can be customized or set to a fixed value using the hyperparameters input. For example, if `train_size = 0.7`, validation size and test size will both be 0.15 and 0.15. When `ts_validation = FALSE`, nrmse_train is the objective function; when `ts_validation = TRUE`, nrmse_val is the objective function.

add_penalty_factor

    Boolean. Add penalty factor hyperparameters to glmnet's penalty.factor to be optimized by nevergrad. Use with caution, because this feature might add too much hyperparameter space and probably requires more iterations to converge.

objective_weights

    Numeric vector. Default to NULL to give equal weights to all objective functions. Order: NRMSE, DECOMP.RSSD, MAPE (when calibration data is provided). When you are not calibrating, only the first 2 values for `objective_weights` must be defined, i.e. set c(2, 1) to give double weight to the 1st (NRMSE). This is an experimental feature. There's no research on optimal weight setting. Subjective weights might strongly bias modeling results.

dt_hyper_fixed   data.frame or named list. Only provide when loading old model results. It consumes hyperparameters from saved csv `pareto_hyperparameters.csv` or JSON file to replicate a model.

rssd_zero_penalty

    Boolean. When TRUE, the objective function DECOMP.RSSD will penalize models with more 0 media effects additionally. In other words, given the same DECOMP.RSSD score, a model with 50% 0-coef variables will get penalized by DECOMP.RSSD * 1.5 (larger error), while another model with no 0-coef variables gets un-penalized with DECOMP.RSSD * 1.

refresh   Boolean. Set to `TRUE` when used in robyn_refresh().

trial   Integer. Which trial are we running? Used to ID each model.

seed   Integer. For reproducible results when running nevergrad and clustering. Each trial will increase the seed by 1 unit (i.e. 10 trials with seed 1 will share 9 results with 10 trials with seed 2).

quiet   Boolean. Keep messages off?

...   Additional parameters passed to robyn_outputs().

inputs   List. Elements to pass sub-functions

Value

List. MMM results with hyperparameters values.

---

robyn_outputs   *Evaluate Models and Output Results into Local Files*

Description

Pack robyn_plots(), robyn_csv(), and robyn_clusters() outcomes on robyn_run() results. When UI=TRUE, enriched OutputModels results with additional plots and objects.

Create a plot to visualize the convergence for each of the datasets when running robyn_run(), especially useful for when using ts_validation. As a reference, the closer the test and validation convergence points are, the better, given the time-series wasn't overfitted.

Usage

```
robyn_outputs(
  InputCollect,
  OutputModels,
  pareto_fronts = "auto",
  calibration_constraint = 0.1,
  plot_folder = NULL,
  plot_folder_sub = NULL,
  plot_pareto = TRUE,
  csv_out = "pareto",
  clusters = TRUE,
  select_model = "clusters",
  ui = FALSE,
  export = TRUE,
  all_sol_json = FALSE,
  quiet = FALSE,
  refresh = FALSE,
  ...
)

## S3 method for class 'robyn_outputs'
print(x, ...)

robyn_csv(
  InputCollect,
  OutputCollect,
  csv_out = NULL,
  export = TRUE,
  calibrated = FALSE
)

pareto_front(xi, yi, pareto_fronts = 1, ...)

robyn_immcarr(
```

```
  InputCollect,
  OutputCollect,
  solID = NULL,
  start_date = NULL,
  end_date = NULL,
  ...
)

robyn_plots(
  InputCollect,
  OutputCollect,
  export = TRUE,
  plot_folder = OutputCollect$plot_folder,
  ...
)

robyn_onepagers(
  InputCollect,
  OutputCollect,
  select_model = NULL,
  quiet = FALSE,
  export = TRUE,
  plot_folder = OutputCollect$plot_folder,
  baseline_level = 0,
  ...
)

ts_validation(OutputModels, quiet = FALSE, ...)

decomp_plot(
  InputCollect,
  OutputCollect,
  solID = NULL,
  exclude = NULL,
  baseline_level = 0
)
```

Arguments

InputCollect, OutputModels

> robyn_inputs() and robyn_run() outcomes.

pareto_fronts   Integer. Number of Pareto fronts for the output. pareto_fronts = 1 returns the best models trading off NRMSE & DECOMP.RSSD. Increase pareto_fronts to get more model choices. pareto_fronts = "auto" selects the min fronts that include at least 100 candidates. To customize this threshold, set value with min_candidates.

calibration_constraint

> Numeric. Default to 0.1 and allows 0.01-0.1. When calibrating, 0.1 means top 10 selection. Lower calibration_constraint increases calibration accuracy.

plot_folder	Character. Path for saving plots and files. Default to robyn_object and saves plot in the same directory as robyn_object.
plot_folder_sub	
	Character. Sub path for saving plots. Will overwrite the default path with timestamp or, for refresh and allocator, simply overwrite files.
plot_pareto	Boolean. Set to FALSE to deactivate plotting and saving model one-pagers. Used when testing models.
csv_out	Character. Accepts "pareto" or "all". Default to "pareto". Set to "all" will output all iterations as csv. Set NULL to skip exports into CSVs.
clusters	Boolean. Apply robyn_clusters() to output models?
select_model	Character vector. Which models (by solID) do you wish to plot the one-pagers and export? Default will take top robyn_clusters() results.
ui	Boolean. Save additional outputs for UI usage. List outcome.
export	Boolean. Export outcomes into local files?
all_sol_json	Logical. Add all pareto solutions to json export?
quiet	Boolean. Keep messages off?
refresh	Boolean. Refresh mode
...	Additional parameters passed to robyn_clusters()
x	robyn_outputs() output.
OutputCollect	robyn_run(..., export = FALSE) output.
calibrated	Logical
xi, yi	Numeric. Coordinates values per observation.
solID	Character vector. Model IDs to plot.
start_date, end_date	
	Character/Date. Dates to consider when calculating immediate and carryover values per channel.
baseline_level	Integer, from 0 to 5. Aggregate baseline variables, depending on the level of aggregation you need. Default is 0 for no aggregation. 1 for Intercept only. 2 adding trend. 3 adding all prophet decomposition variables. 4. Adding contextual variables. 5 Adding organic variables. Results will be reflected on the waterfall chart.
exclude	Character vector. Manually exclude variables from plot.

Value

(Invisible) list. Class: robyn_outputs. Contains processed results based on robyn_run() results.

Invisible NULL.

Invisible list with ggplot plots.

Invisible list with patchwork plot(s).

Invisible list with ggplot plots.

---

robyn_refresh   *Build Refresh Model*

Description

robyn_refresh() builds updated models based on the previously built models saved in the Robyn.RDS object specified in robyn_object. For example, when updating the initial build with 4 weeks of new data, robyn_refresh() consumes the selected model of the initial build, sets lower and upper bounds of hyperparameters for the new build around the selected hyperparameters of the previous build, stabilizes the effect of baseline variables across old and new builds, and regulates the new effect share of media variables towards the latest spend level. It returns the aggregated results with all previous builds for reporting purposes and produces reporting plots.

You must run robyn_save() to select and save an initial model first, before refreshing.

When should robyn_refresh() **NOT be used:** The robyn_refresh() function is suitable for updating within "reasonable periods". Two situations are considered better to rebuild model instead of refreshing:

1. Most data is new: If initial model was trained with 100 weeks worth of data but we add +50 weeks of new data.

2. New variables are added: If initial model had less variables than the ones we want to start using on new refresh model.

Usage

```
robyn_refresh(
  json_file = NULL,
  robyn_object = NULL,
  dt_input = NULL,
  dt_holidays = Robyn::dt_prophet_holidays,
  refresh_steps = 4,
  refresh_mode = "manual",
  refresh_iters = 1000,
  refresh_trials = 3,
  bounds_freedom = NULL,
  plot_folder = NULL,
  plot_pareto = TRUE,
  version_prompt = FALSE,
  export = TRUE,
  calibration_input = NULL,
  objective_weights = NULL,
  ...
)

## S3 method for class 'robyn_refresh'
print(x, ...)
```

```
## S3 method for class 'robyn_refresh'
plot(x, ...)
```

Arguments

`json_file`	Character. JSON file to import previously exported inputs or recreate a model. To generate this file, use robyn_write(). If you didn't export your data in the json file as "raw_data", `dt_input` must be provided; `dt_holidays` input is optional.
`robyn_object`	Character or List. Path of the Robyn.RDS object that contains all previous modeling information or the imported list.
`dt_input`	data.frame. Should include all previous data and newly added data for the refresh.
`dt_holidays`	data.frame. Raw input holiday data. Load standard Prophet holidays using `data("dt_prophet_holidays")`.
`refresh_steps`	Integer. It controls how many time units the refresh model build move forward. For example, `refresh_steps = 4` on weekly data means the `InputCollect$window_start` & `InputCollect$window_end` move forward 4 weeks. If `refresh_steps` is smaller than the number of newly provided data points, then Robyn would only use the first N steps of the new data.
`refresh_mode`	Character. Options are "auto" and "manual". In auto mode, the robyn_refresh() function builds refresh models with given `refresh_steps` repeatedly until there's no more data available. I manual mode, the robyn_refresh() only moves forward `refresh_steps` only once. "auto" mode has been deprecated when using `json_file` input.
`refresh_iters`	Integer. Iterations per refresh. Rule of thumb is, the more new data added, the more iterations needed. More reliable recommendation still needs to be investigated.
`refresh_trials`	Integer. Trials per refresh. Defaults to 5 trials. More reliable recommendation still needs to be investigated.
`bounds_freedom`	Numeric. Percentage of freedom we'd like to allow for the new hyperparameters values compared with the model to be refreshed. If set to NULL (default) the value will be calculated as refresh_steps / rollingWindowLength. Applies to all hyperparameters.
`plot_folder`	Character. Path for saving plots and files. Default to `robyn_object` and saves plot in the same directory as `robyn_object`.
`plot_pareto`	Boolean. Set to FALSE to deactivate plotting and saving model one-pagers. Used when testing models.
`version_prompt`	Logical. If FALSE, the model refresh version will be selected based on the smallest combined error of normalized NRMSE, DECOMP.RSSD, MAPE. If TRUE, a prompt will be presented to the user to select one of the refreshed models (one-pagers and Pareto CSV files will already be generated).
`export`	Boolean. Export outcomes into local files?

calibration_input

> data.frame. Optional. Provide experimental results to calibrate. Your input should include the following values for each experiment: channel, liftStartDate, liftEndDate, liftAbs, spend, confidence, metric. You can calibrate any spend or organic variable with a well designed experiment. You can also use experimental results from multiple channels; to do so, provide concatenated channel value, i.e. "channel_A+channel_B". Check "Guide for calibration source" section.

objective_weights

> Numeric vector. Default to NULL to give equal weights to all objective functions. Order: NRMSE, DECOMP.RSSD, MAPE (when calibration data is provided). When you are not calibrating, only the first 2 values for `objective_weights` must be defined, i.e. set c(2, 1) to give double weight to the 1st (NRMSE). This is an experimental feature. There's no research on optimal weight setting. Subjective weights might strongly bias modeling results.

...

> Additional parameters to overwrite original custom parameters passed into initial model.

x

> robyn_refresh() output.

Value

List. The Robyn object, class `robyn_refresh`.

List. Same as `robyn_run()` but with refreshed models.

Examples

```
## Not run:
# Loading dummy data
data("dt_simulated_weekly")
data("dt_prophet_holidays")
# Set the (pre-trained and exported) Robyn model JSON file
json_file <- "~/Robyn_202208081444_init/RobynModel-2_55_4.json"

# Run \code{robyn_refresh()} with 13 weeks cadence in auto mode
Robyn <- robyn_refresh(
  json_file = json_file,
  dt_input = dt_simulated_weekly,
  dt_holidays = Robyn::dt_prophet_holidays,
  refresh_steps = 13,
  refresh_mode = "auto",
  refresh_iters = 200,
  refresh_trials = 5
)

# Run \code{robyn_refresh()} with 4 weeks cadence in manual mode
json_file2 <- "~/Robyn_202208081444_init/Robyn_202208090847_rf/RobynModel-1_2_3.json"
Robyn <- robyn_refresh(
  json_file = json_file2,
  dt_input = dt_simulated_weekly,
  dt_holidays = Robyn::dt_prophet_holidays,
  refresh_steps = 4,
```

```
  refresh_mode = "manual",
  refresh_iters = 200,
  refresh_trials = 5
)

## End(Not run)
```

---

robyn_response   *Response and Saturation Curves*

Description

robyn_response() returns the response for a given spend level of a given paid_media_vars from a selected model result and selected model build (initial model, refresh model, etc.).

Usage

```
robyn_response(
  InputCollect = NULL,
  OutputCollect = NULL,
  json_file = NULL,
  select_build = NULL,
  select_model = NULL,
  metric_name = NULL,
  metric_value = NULL,
  date_range = NULL,
  dt_hyppar = NULL,
  dt_coef = NULL,
  quiet = FALSE,
  ...
)
```

Arguments

InputCollect	List. Contains all input parameters for the model. Required when robyn_object is not provided.
OutputCollect	List. Containing all model result. Required when robyn_object is not provided.
json_file	Character. JSON file to import previously exported inputs or recreate a model. To generate this file, use robyn_write(). If you didn't export your data in the json file as "raw_data", dt_input must be provided; dt_holidays input is optional.
select_build	Integer. Default to the latest model build. select_build = 0 selects the initial model. select_build = 1 selects the first refresh model.

select_model	Character. A model SolID. When robyn_object is provided, select_model defaults to the already selected SolID. When robyn_object is not provided, select_model must be provided with InputCollect and OutputCollect, and must be one of OutputCollect$allSolutions.
metric_name	A character. Selected media variable for the response. Must be one value from paid_media_spends, paid_media_vars or organic_vars
metric_value	Numeric. Desired metric value to return a response for.
date_range	Character. Date(s) to apply adstocked transformations and pick mean spends per channel. Set one of: "all", "last", or "last_n" (where n is the last N dates available), date (i.e. "2022-03-27"), or date range (i.e. c("2022-01-01", "2022-12-31")). Default to "all".
dt_hyppar	A data.frame. When json_file is not provided, use dt_hyppar = OutputCollect$resultHypParam. It must be provided along select_model, dt_coef and InputCollect.
dt_coef	A data.frame. When json_file is not provided, use dt_coef = OutputCollect$xDecompAgg. It must be provided along select_model, dt_hyppar and InputCollect.
quiet	Boolean. Keep messages off?
...	Additional parameters passed to robyn_outputs().

Value

List. Response value and plot. Class: robyn_response.

Examples

```
## Not run:
# Having InputCollect and OutputCollect objects
## Recreate original saturation curve
Response <- robyn_response(
  InputCollect = InputCollect,
  OutputCollect = OutputCollect,
  select_model = select_model,
  metric_name = "facebook_S"
)
Response$plot

## Or you can call a JSON file directly (a bit slower)
# Response <- robyn_response(
#   json_file = "your_json_path.json",
#   dt_input = dt_simulated_weekly,
#   dt_holidays = dt_prophet_holidays,
#   metric_name = "facebook_S"
# )

## Get the "next 100 dollar" marginal response on Spend1
Spend1 <- 20000
Response1 <- robyn_response(
  InputCollect = InputCollect,
  OutputCollect = OutputCollect,
  select_model = select_model,
```

```
  metric_name = "facebook_S",
  metric_value = Spend1, # total budget for date_range
  date_range = "last_1" # last two periods
)
Response1$plot

Spend2 <- Spend1 + 100
Response2 <- robyn_response(
  InputCollect = InputCollect,
  OutputCollect = OutputCollect,
  select_model = select_model,
  metric_name = "facebook_S",
  metric_value = Spend2,
  date_range = "last_1"
)
# ROAS for the 100$ from Spend1 level
(Response2$response_total - Response1$response_total) / (Spend2 - Spend1)

## Get response from for a given budget and date_range
Spend3 <- 100000
Response3 <- robyn_response(
  InputCollect = InputCollect,
  OutputCollect = OutputCollect,

---

robyn_run   *Robyn Modelling Function*

Description

robyn_run() consumes robyn_input() outputs, runs robyn_mmm(), and collects all modeling results.

Usage

```
robyn_run(
  InputCollect = NULL,
  dt_hyper_fixed = NULL,
  json_file = NULL,
  ts_validation = FALSE,
  add_penalty_factor = FALSE,
  refresh = FALSE,
  seed = 123L,
  quiet = FALSE,
  cores = NULL,
  trials = 5,
  iterations = 2000,
  rssd_zero_penalty = TRUE,
  objective_weights = NULL,
  nevergrad_algo = "TwoPointsDE",
  intercept = TRUE,
  intercept_sign = "non_negative",
  lambda_control = NULL,
  outputs = FALSE,
  ...
)

## S3 method for class 'robyn_models'
print(x, ...)
```

Arguments

InputCollect   List. Contains all input parameters for the model. Required when robyn_object is not provided.

dt_hyper_fixed data.frame or named list. Only provide when loading old model results. It consumes hyperparameters from saved csv pareto_hyperparameters.csv or JSON file to replicate a model.

json_file   Character. JSON file to import previously exported inputs or recreate a model.
                    To generate this file, use robyn_write(). If you didn't export your data in
                    the json file as "raw_data", dt_input must be provided; dt_holidays input is
                    optional.

ts_validation   Boolean. When set to TRUE, Robyn will split data by test, train, and validation
                    partitions to validate the time series. By default the "train_size" range is set to
                    c(0.5, 0.8), but it can be customized or set to a fixed value using the hyper-
                    parameters input. For example, if train_size = 0.7, validation size and test
                    size will both be 0.15 and 0.15. When ts_validation = FALSE, nrmse_train is
                    the objective function; when ts_validation = TRUE, nrmse_val is the objective
                    function.

add_penalty_factor
                    Boolean. Add penalty factor hyperparameters to glmnet's penalty.factor to be
                    optimized by nevergrad. Use with caution, because this feature might add too
                    much hyperparameter space and probably requires more iterations to converge.

refresh   Boolean. Set to TRUE when used in robyn_refresh().

seed   Integer. For reproducible results when running nevergrad and clustering. Each
                    trial will increase the seed by 1 unit (i.e. 10 trials with seed 1 will share 9 results
                    with 10 trials with seed 2).

quiet   Boolean. Keep messages off?

cores   Integer. Default to parallel::detectCores() - 1 (all cores except one). Set
                    to 1 if you want to turn parallel computing off.

trials   Integer. Recommended 5 for default nevergrad_algo = "TwoPointsDE".

iterations   Integer. Recommended 2000 for default when using nevergrad_algo = "TwoPointsDE".

rssd_zero_penalty
                    Boolean. When TRUE, the objective function DECOMP.RSSD will penalize
                    models with more 0 media effects additionally. In other words, given the same
                    DECOMP.RSSD score, a model with 50% 0-coef variables will get penalized
                    by DECOMP.RSSD * 1.5 (larger error), while another model with no 0-coef
                    variables gets un-penalized with DECOMP.RSSD * 1.

objective_weights
                    Numeric vector. Default to NULL to give equal weights to all objective func-
                    tions. Order: NRMSE, DECOMP.RSSD, MAPE (when calibration data is pro-
                    vided). When you are not calibrating, only the first 2 values for objective_weights
                    must be defined, i.e. set c(2, 1) to give double weight to the 1st (NRMSE). This
                    is an experimental feature. There's no research on optimal weight setting. Sub-
                    jective weights might strongly bias modeling results.

nevergrad_algo   Character. Default to "TwoPointsDE". Options are c("DE","TwoPointsDE",
                    "OnePlusOne", "DoubleFastGADiscreteOnePlusOne","DiscreteOnePlusOne",
                    "PortfolioDiscreteOnePlusOne", "NaiveTBPSA","cGA", "RandomSearch").

intercept   Boolean. Should intercept(s) be fitted (default=TRUE) or set to zero (FALSE).

intercept_sign   Character. Choose one of "non_negative" (default) or "unconstrained". By de-
                    fault, if intercept is negative, Robyn will drop intercept and refit the model. Con-
                    sider changing intercept_sign to "unconstrained" when there are context_vars
                    with large positive values.

lambda_control	Deprecated in v3.6.0.
outputs	Boolean. If set to TRUE, will run robyn_run() and robyn_outputs(), returning a list with OutputModels and OutputCollect results.
...	Additional parameters passed to robyn_outputs().
x	robyn_models() output.

Value

List. Class: robyn_models. Contains the results of all trials and iterations modeled.

List. Contains all trained models. Class: robyn_models.

Examples

```
## Not run:
# Having InputCollect results
OutputModels <- robyn_run(
  InputCollect = InputCollect,
  cores = 2,
  iterations = 200,
  trials = 1
)

## End(Not run)
```

---

robyn_save   *Export Robyn Model to Local File [DEPRECATED]*

Description

Use robyn_save() to select and save as .RDS file the initial model.

Usage

```
robyn_save(
  InputCollect,
  OutputCollect,
  robyn_object = NULL,
  select_model = NULL,
  dir = OutputCollect$plot_folder,
  quiet = FALSE,
  ...
)

## S3 method for class 'robyn_save'
print(x, ...)

## S3 method for class 'robyn_save'
```

```
plot(x, ...)

robyn_load(robyn_object, select_build = NULL, quiet = FALSE)
```

Arguments

`InputCollect`	List. Contains all input parameters for the model. Required when `robyn_object` is not provided.
`OutputCollect`	List. Containing all model result. Required when `robyn_object` is not provided.
`robyn_object`	Character or List. Path of the `Robyn.RDS` object that contains all previous modeling information or the imported list.
`select_model`	Character. A model SolID. When `robyn_object` is provided, `select_model` defaults to the already selected SolID. When `robyn_object` is not provided, `select_model` must be provided with `InputCollect` and `OutputCollect`, and must be one of `OutputCollect$allSolutions`.
`dir`	Character. Existing directory to export JSON file to.
`quiet`	Boolean. Keep messages off?
`...`	Additional parameters passed to `robyn_outputs()`.
`x`	`robyn_save()` output.
`select_build`	Integer. Default to the latest model build. `select_build = 0` selects the initial model. `select_build = 1` selects the first refresh model.

Value

(Invisible) list with filename and summary. Class: `robyn_save`.

(Invisible) list with imported results

---

robyn_train	*Train Robyn Models*

Description

`robyn_train()` consumes output from `robyn_input()` and runs the `robyn_mmm()` on each trial.

Usage

```
robyn_train(
  InputCollect,
  hyper_collect,
  cores,
  iterations,
  trials,
  intercept_sign,
  intercept,
```

```
    nevergrad_algo,
    dt_hyper_fixed = NULL,
    ts_validation = TRUE,
    add_penalty_factor = FALSE,
    objective_weights = NULL,
    rssd_zero_penalty = TRUE,
    refresh = FALSE,
    seed = 123,
    quiet = FALSE
)
```

Arguments

InputCollect	List. Contains all input parameters for the model. Required when `robyn_object` is not provided.
hyper_collect	List. Containing hyperparameter bounds. Defaults to `InputCollect$hyperparameters`.
cores	Integer. Default to `parallel::detectCores() - 1` (all cores except one). Set to 1 if you want to turn parallel computing off.
iterations	Integer. Recommended 2000 for default when using `nevergrad_algo = "TwoPointsDE"`.
trials	Integer. Recommended 5 for default `nevergrad_algo = "TwoPointsDE"`.
intercept_sign	Character. Choose one of "non_negative" (default) or "unconstrained". By default, if intercept is negative, Robyn will drop intercept and refit the model. Consider changing intercept_sign to "unconstrained" when there are `context_vars` with large positive values.
intercept	Boolean. Should intercept(s) be fitted (default=TRUE) or set to zero (FALSE).
nevergrad_algo	Character. Default to "TwoPointsDE". Options are c("DE","TwoPointsDE", "OnePlusOne", "DoubleFastGADiscreteOnePlusOne","DiscreteOnePlusOne", "PortfolioDiscreteOnePlusOne", "NaiveTBPSA","cGA", "RandomSearch").
dt_hyper_fixed	data.frame or named list. Only provide when loading old model results. It consumes hyperparameters from saved csv `pareto_hyperparameters.csv` or JSON file to replicate a model.
ts_validation	Boolean. When set to TRUE, Robyn will split data by test, train, and validation partitions to validate the time series. By default the "train_size" range is set to `c(0.5, 0.8)`, but it can be customized or set to a fixed value using the hyperparameters input. For example, if `train_size = 0.7`, validation size and test size will both be 0.15 and 0.15. When `ts_validation = FALSE`, nrmse_train is the objective function; when `ts_validation = TRUE`, nrmse_val is the objective function.
add_penalty_factor	
	Boolean. Add penalty factor hyperparameters to glmnet's penalty.factor to be optimized by nevergrad. Use with caution, because this feature might add too much hyperparameter space and probably requires more iterations to converge.
objective_weights	
	Numeric vector. Default to NULL to give equal weights to all objective functions. Order: NRMSE, DECOMP.RSSD, MAPE (when calibration data is provided). When you are not calibrating, only the first 2 values for `objective_weights`

must be defined, i.e. set c(2, 1) to give double weight to the 1st (NRMSE). This
is an experimental feature. There's no research on optimal weight setting. Sub-
jective weights might strongly bias modeling results.

rssd_zero_penalty

Boolean. When TRUE, the objective function DECOMP.RSSD will penalize
models with more 0 media effects additionally. In other words, given the same
DECOMP.RSSD score, a model with 50% 0-coef variables will get penalized
by DECOMP.RSSD * 1.5 (larger error), while another model with no 0-coef
variables gets un-penalized with DECOMP.RSSD * 1.

refresh   Boolean. Set to TRUE when used in robyn_refresh().

seed   Integer. For reproducible results when running nevergrad and clustering. Each
                 trial will increase the seed by 1 unit (i.e. 10 trials with seed 1 will share 9 results
                 with 10 trials with seed 2).

quiet   Boolean. Keep messages off?

Value

List. Iteration results to include in robyn_run() results.

---

robyn_update	*Update Robyn Version*

Description

Update Robyn version from Github repository for latest "dev" version or from CRAN for latest
"stable" version.

Usage

```
robyn_update(dev = TRUE, ...)
```

Arguments

dev   Boolean. Dev version? If not, CRAN version.

...   Parameters to pass to remotes::install_github or utils::install.packages,
                 depending on dev parameter.

Value

Invisible NULL.

---

robyn_write *Import and Export Robyn JSON files*

Description

robyn_write() generates light JSON files with all the information required to replicate Robyn models. Depending on user inputs, there are 3 use cases: only the inputs data, input data + modeling results data, and input data, modeling results + specifics of a single selected model. To replicate a model, you must provide InputCollect, OutputCollect, and, if OutputCollect contains more than one model, the select_model.

Usage

```
robyn_write(
  InputCollect,
  OutputCollect = NULL,
  select_model = NULL,
  dir = OutputCollect$plot_folder,
  add_data = TRUE,
  export = TRUE,
  quiet = FALSE,
  pareto_df = NULL,
  ...
)

## S3 method for class 'robyn_write'
print(x, ...)

robyn_read(json_file = NULL, step = 1, quiet = FALSE, ...)

## S3 method for class 'robyn_read'
print(x, ...)

robyn_recreate(json_file, quiet = FALSE, ...)
```

Arguments

InputCollect	robyn_inputs() output.
OutputCollect	robyn_run(..., export = FALSE) output.
select_model	Character. Which model ID do you want to export into the JSON file?
dir	Character. Existing directory to export JSON file to.
add_data	Boolean. Include raw dataset. Useful to recreate models with a single file containing all the required information (no need of CSV).
export	Boolean. Export outcomes into local files?
quiet	Boolean. Keep messages off?

pareto_df	Dataframe. Save all pareto solutions to json file.
...	Additional parameters to export into a custom Extras element.
x	`robyn_read()` or `robyn_write()` output.
json_file	Character. JSON file name to read and import.
step	Integer. 1 for import only and 2 for import and output.

Value

(invisible) List. Contains all inputs and outputs of exported model. Class: `robyn_write`.

Examples

```
## Not run:
InputCollectJSON <- robyn_inputs(
  dt_input = Robyn::dt_simulated_weekly,
  json_file = "~/Desktop/RobynModel-1_29_12.json"
)
print(InputCollectJSON)

## End(Not run)
```

---

saturation_hill   *Hill Saturation Transformation*

Description

`saturation_hill` is a two-parametric version of the Hill function that allows the saturation curve to flip between S and C shape.

Produce example plots for the Hill saturation curve.

Usage

```
saturation_hill(x, alpha, gamma, x_marginal = NULL)

plot_saturation(plot = TRUE)
```

Arguments

x	Numeric vector.
alpha	Numeric. Alpha controls the shape of the saturation curve. The larger the alpha, the more S-shape. The smaller, the more C-shape.
gamma	Numeric. Gamma controls the inflexion point of the saturation curve. The larger the gamma, the later the inflexion point occurs.
x_marginal	Numeric. When provided, the function returns the Hill-transformed value of the x_marginal input.
plot	Boolean. Do you wish to return the plot?

Value

List. x_saturated as transformed values and inflexion point

See Also

Other Transformations: `adstock_geometric()`, `transformations`

Examples

```
saturation_hill(c(100, 150, 170, 190, 200), alpha = 3, gamma = 0.5)
```

---

set_default_hyppar   *Set default hyperparameters*

Description

For quick setting of hyperparameter ranges.

Usage

```
set_default_hyppar(
  adstock = NULL,
  all_media = NULL,
 list_default = list(alpha = c(0.5, 3), gamma = c(0.01, 1), theta = c(0, 0.8), shape =
    c(0, 10), scale = c(0, 0.1), train_size = c(0.5, 0.9))
)
```

Arguments

adstock	Character. InputCollect$adstock
all_media	Character. Provide InputCollect$all_media.
list_default	A List. Default ranges for hyperparameters.

Value

List. Expanded range of hyperparameters for all media.

---

set_holidays   *Detect and set date variable interval*

Description

Robyn only accepts daily, weekly and monthly data. This function is only called in robyn_engineering().

Usage

```
set_holidays(dt_transform, dt_holidays, intervalType)
```

Arguments

dt_transform	A data.frame. Transformed input data.
dt_holidays	A data.frame. Raw input holiday data.
intervalType	A character. Accepts one of the values: c("day","week","month")

Value

List. Containing the all spend-exposure model results.

---

transformations   *Michaelis-Menten Transformation*

Description

The Michaelis-Menten mic_men() function is used to fit the spend exposure relationship for paid media variables, when exposure metrics like impressions, clicks or GRPs are provided in paid_media_vars instead of spend metric.

Usage

```
mic_men(x, Vmax, Km, reverse = FALSE)

run_transformations(
  all_media,
  window_start_loc,
  window_end_loc,
  dt_mod,
  adstock,
  dt_hyppar,
  ...
)
```

Arguments

x	Numeric value or vector. Input media spend when reverse = FALSE. Input media exposure metrics (impression, clicks, GRPs, etc.) when reverse = TRUE.
Vmax	Numeric Indicates maximum rate achieved by the system.
Km	Numeric. The Michaelis constant.
reverse	Boolean. Input media spend when reverse = FALSE. Input media exposure metrics (impression, clicks, GRPs etc.) when reverse = TRUE.
all_media	Character. Vector of all selected paid media variable names.
window_start_loc	
	Integer. Rolling window start location.
window_end_loc	Integer. Rolling window end location.
dt_mod	dataframe. Transformed input table for transformation.
adstock	Character. Adstock config.
dt_hyppar	data.frame. All hyperparaters for provided media.
...	Additional parameters passed to prophet functions.

Value

Numeric values. Transformed values.

See Also

Other Transformations: adstock_geometric(), saturation_hill()

Examples

```
mic_men(x = 5:10, Vmax = 5, Km = 0.5)
```
