

Package ‘SpaDES.core’

July 21, 2025

Type Package

Title Core Utilities for Developing and Running Spatially Explicit
Discrete Event Models

Description Provides the core framework for a discrete event system to implement a complete data-to-decisions, reproducible workflow. The core components facilitate the development of modular pieces, and enable the user to include additional functionality by running user-built modules. Includes conditional scheduling, restart after interruption, packaging of reusable modules, tools for developing arbitrary automated workflows, automated interweaving of modules of different temporal resolution, and tools for visualizing and understanding the within-project dependencies. The suggested package 'NLMR' can be installed from the repository (<<https://PredictiveEcology.r-universe.dev>>).

SpaDES.core-package	<i>Categorized overview of the SpaDES.core package</i>
---------------------	--

Description

This package allows implementation a variety of simulation-type models, with a focus on spatially explicit models. The core simulation components are built upon a discrete event simulation framework that facilitates modularity, and easily enables the user to include additional functionality by running user-built simulation modules. Included are numerous tools to visualize various spatial data formats, as well as non-spatial data. Much work has been done to speed up the core of the DES, with current benchmarking as low as 56 microseconds overhead for each event (including scheduling, sorting event queue, spawning event etc.) or 38 microseconds if there is no sorting (i.e., no sorting occurs under simple conditions). Under most event conditions, therefore, the DES itself will contribute very minimally compared to the content of the events, which may often be milliseconds to many seconds each event.

Details

1 Spatial discrete event simulation (SpaDES)

A collection of top-level functions for doing spatial discrete event simulation.

1.1 Simulations: There are two workhorse functions that initialize and run a simulation, and third function for doing multiple spades runs:

<code>simInit()</code>	Initialize a new simulation
<code>spades()</code>	Run a discrete event simulation
<code>experiment</code>	In SpaDES.experiment package. Run multiple <code>spades()</code> calls
<code>experiment2</code>	In SpaDES.experiment package. Run multiple <code>spades()</code> calls

1.2 Events: Within a module, important simulation functions include:

<code>scheduleEvent()</code>	Schedule a simulation event
<code>scheduleConditionalEvent()</code>	Schedule a conditional simulation event
<code>removeEvent</code>	Remove an event from the simulation queue (not yet implemented)

2 The simList object class

The principle exported object class is the `simList`. All SpaDES simulations operate on this object class.

`simList()` The `simList` class

3 simList methods

Collections of commonly used functions to retrieve or set slots (and their elements) of a `simList()` object are summarized further below.

3.1 Simulation parameters:

<code>globals()</code>	List of global simulation parameters.
<code>params()</code>	Nested list of all simulation parameter.
<code>P()</code>	Namespaced version of <code>params()</code> (i.e., do not have to specify module name).

3.2 loading from disk, saving to disk:

<code>inputs()</code>	List of loaded objects used in simulation. (advanced)
<code>outputs()</code>	List of objects to save during simulation. (advanced)

3.3 objects in the simList:

<code>ls()</code> , <code>objects()</code>	Names of objects referenced by the simulation environment.
<code>ls.str()</code>	List the structure of the <code>simList</code> objects.
<code>objs()</code>	List of objects referenced by the simulation environment.

3.4 Simulation paths: Accessor functions for the paths slot and its elements.

<code>cachePath()</code>	Global simulation cache path.
<code>modulePath()</code>	Global simulation module path.

<code>inputPath()</code>	Global simulation input path.
<code>outputPath()</code>	Global simulation output path.
<code>rasterPath()</code>	Global simulation temporary raster path.
<code>paths()</code>	Global simulation paths (cache, modules, inputs, outputs, rasters).

3.5 Simulation times: Accessor functions for the simtimes slot and its elements.

<code>time()</code>	Current simulation time, in units of longest module.
<code>start()</code>	Simulation start time, in units of longest module.
<code>end()</code>	Simulation end time, in units of longest module.
<code>times()</code>	List of all simulation times (current, start, end), in units of longest module..

3.6 Simulation event queues: Accessor functions for the events and completed slots. By default, the event lists are shown when the simList object is printed, thus most users will not require direct use of these methods.

<code>events()</code>	Scheduled simulation events (the event queue). (advanced)
<code>current()</code>	Currently executing event. (advanced)
<code>completed()</code>	Completed simulation events. (advanced)
<code>elapsedTime()</code>	The amount of clock time that modules & events use

3.7 Modules, dependencies, packages: Accessor functions for the depends, modules, and .loadOrder slots. These are included for advanced users.

<code>depends()</code>	List of simulation module dependencies. (advanced)
<code>modules()</code>	List of simulation modules to be loaded. (advanced)
<code>packages()</code>	Vector of required R libraries of all modules. (advanced)

3.8 simList environment: The `simList()` has a slot called `.xData` which is an environment. All objects in the `simList` are actually in this environment, i.e., the `simList` is not a list. In R, environments use pass-by-reference semantics, which means that copying a `simList` object using normal R assignment operation (e.g., `sim2 <- sim1`), will not copy the objects contained within the `.xData` slot. The two objects (`sim1` and `sim2`) will share identical objects within that slot. Sometimes, this not desired, and a true copy is required.

<code>envir()</code>	Access the environment of the <code>simList</code> directly (advanced)
<code>copy()</code>	Deep copy of a <code>simList</code> . (advanced)

3.9 Checkpointing:

Accessor method	Module	Description
<code>checkpointFile()</code>	checkpoint	Name of the checkpoint file. (advanced)
<code>checkpointInterval()</code>	checkpoint	The simulation checkpoint interval. (advanced)

3.10 Progress Bar:

<code>progressType()</code>	<code>.progress</code>	Type of graphical progress bar used. (advanced)
<code>progressInterval()</code>	<code>.progress</code>	Interval for the progress bar. (advanced)

4 Module operations

4.1 Creating, distributing, and downloading modules: Modules are the basic unit of SpaDES. These are generally created and stored locally, or are downloaded from remote repositories, including our [SpaDES-modules](#) repository on GitHub.

<code>checksums()</code>	Verify (and optionally write) checksums for a module's data files.
<code>downloadModule()</code>	Open all modules nested within a base directory.
<code>getModuleVersion()</code>	Get the latest module version # from module repository.
<code>newModule()</code>	Create new module from template.
<code>newModuleDocumentation()</code>	Create empty documentation for a new module.
<code>openModules()</code>	Open all modules nested within a base directory.
<code>moduleMetadata()</code>	Shows the module metadata.
<code>zipModule()</code>	Zip a module and its associated files.

4.2 Module metadata: Each module requires several items to be defined. These comprise the metadata for that module (including default parameter specifications, inputs and outputs), and are currently written at the top of the module's .R file.

<code>defineModule()</code>	Define the module metadata
<code>defineParameter()</code>	Specify a parameter's name, value and set a default
<code>expectsInput()</code>	Specify an input object's name, class, description, sourceURL and other specifications
<code>createsOutput()</code>	Specify an output object's name, class, description and other specifications

There are also accessors for many of the metadata entries:

<code>timeunit()</code>	Accesses metadata of same name
<code>citation()</code>	Accesses metadata of same name
<code>documentation()</code>	Accesses metadata of same name
<code>reqdPkgs()</code>	Accesses metadata of same name
<code>inputObjects()</code>	Accesses metadata of same name
<code>outputObjects()</code>	Accesses metadata of same name

4.3 Module dependencies: Once a set of modules have been chosen, the dependency information is automatically calculated once `simInit` is run. There are several functions to assist with dependency information:

<code>depsEdgeList()</code>	Build edge list for module dependency graph
<code>depsGraph()</code>	Build a module dependency graph using <code>igraph</code>

5 Module functions

A collection of functions that help with making modules can be found in the suggested `SpaDES.tools` package, and are summarized below.

5.1 Spatial spreading/distances methods: Spatial contagion is a key phenomenon for spatially explicit simulation models. Contagion can be modelled using discrete approaches or continuous approaches. Several `SpaDES.tools` functions assist with these:

<code>SpaDES.tools::adj()</code>	An optimized (i.e., faster) version of <code>terra::adjacent()</code>
<code>SpaDES.tools::cir()</code>	Identify pixels in a circle around a <code>SpatialPoints*</code> object
<code>directionFromEachPoint()</code>	Fast calculation of direction and distance surfaces
<code>SpaDES.tools::distanceFromEachPoint()</code>	Fast calculation of distance surfaces
<code>SpaDES.tools::rings()</code>	Identify rings around focal cells (e.g., buffers and donuts)
<code>SpaDES.tools::spokes()</code>	Identify outward radiating spokes from initial points
<code>SpaDES.tools::spread()</code>	Contagious cellular automata
<code>SpaDES.tools::spread2()</code>	Contagious cellular automata, different algorithm, more robust
<code>SpaDES.tools::wrap()</code>	Create a torus from a grid

5.2 Spatial agent methods: Agents have several methods and functions specific to them:

<code>SpaDES.tools::crw()</code>	Simple correlated random walk function
<code>SpaDES.tools::heading()</code>	Determines the heading between <code>SpatialPoints*</code>
<code>quickPlot::makeLines()</code>	Makes <code>SpatialLines</code> object for, e.g., drawing arrows
<code>move()</code>	A meta function that can currently only take "crw"
<code>specificNumPerPatch()</code>	Initiate a specific number of agents per patch

5.3 GIS operations: In addition to the vast amount of GIS operations available in R (mostly from contributed packages such as `sf`, `terra`, (also `sp`, `raster`), `maps`, `maptools` and many others), we provide the following GIS-related functions:

`equalExtent()` Assess whether a list of extents are all equal

5.4 'Map-reduce'-type operations: These functions convert between reduced and mapped representations of the same data. This allows compact representation of, e.g., rasters that have many individual pixels that share identical information.

`SpaDES.tools::rasterizeReduced()` Convert reduced representation to full raster.

5.5 Colours in Raster* objects: We likely will not want the default colours for every map. Here are several helper functions to add to, set and get colours of `Raster*` objects:

<code>setColors()</code>	Set colours for plotting <code>Raster*</code> objects
<code>getColors()</code>	Get colours in a <code>Raster*</code> objects
<code>divergentColors()</code>	Create a colour palette with diverging colours around a middle

5.6 Random Map Generation: It is often useful to build dummy maps with which to build simulation models before all data are available. These dummy maps can later be replaced with actual data maps.

<code>SpaDES.tools::neutralLandscapeMap()</code>	Creates a random map using Gaussian random fields
<code>SpaDES.tools::randomPolygons()</code>	Creates a random polygon with specified number of classes

5.7 Checking for the existence of objects: SpaDES modules will often require the existence of objects in the `simList`. These are helpers for assessing this:

<code>checkObject()</code>	Check for a existence of an object within a <code>simList</code>
<code>reproducible::checkPath()</code>	Checks the specified filepath for formatting consistencies

5.8 SELES-type approach to simulation: These functions are essentially skeletons and are not fully implemented. They are intended to make translations from SELES (<https://www.gowlland.ca/>). You must know how to use SELES for these to be useful:

<code>agentLocation()</code>	Agent location
<code>SpaDES.tools::initiateAgents()</code>	Initiate agents into a <code>SpatialPointsDataFrame</code>
<code>numAgents()</code>	Number of agents
<code>probInit()</code>	Probability of initiating an agent or event
<code>transitions()</code>	Transition probability

5.9 Miscellaneous: Functions that may be useful within a SpaDES context:

<code>SpaDES.tools::inRange()</code>	Test whether a number lies within range <code>[a, b]</code>
<code>layerNames()</code>	Get layer names for numerous object classes
<code>numLayers()</code>	Return number of layers
<code>paddedFloatToChar()</code>	Wrapper for padding (e.g., zeros) floating numbers to character

6 Caching simulations and simulation components

Simulation caching uses the reproducible package.

Caching can be done in a variety of ways, most of which are up to the module developer. However, the one most common usage would be to cache a simulation run. This might be useful if a simulation is very long, has been run once, and the goal is just to retrieve final results. This would be an alternative to manually saving the outputs.

See example in `spades()`, achieved by using `cache = TRUE` argument.

<code>reproducible::Cache()</code>	Caches a function, but often accessed as argument in <code>spades()</code>
<code>reproducible::showCache()</code>	Shows information about the objects in the cache
<code>reproducible::clearCache()</code>	Removes objects from the cache
<code>reproducible::keepCache()</code>	Keeps only the objects described

A module developer can build caching into their module by creating cached versions of their functions.

7 Plotting

Much of the underlying plotting functionality is provided by `quickPlot`.

There are several user-accessible plotting functions that are optimized for modularity and speed of plotting:

Commonly used:

`Plot()` The workhorse plotting function

Simulation diagrams:

<code>eventDiagram()</code>	Gantt chart representing the events in a completed simulation.
<code>moduleDiagram()</code>	Network diagram of simplified module (object) dependencies.
<code>objectDiagram()</code>	Sequence diagram of detailed object dependencies.

Other useful plotting functions:

<code>clearPlot()</code>	Helpful for resolving many errors
<code>clickValues()</code>	Extract values from a raster object at the mouse click location(s)
<code>clickExtent()</code>	Zoom into a raster or polygon map that was plotted with <code>Plot()</code>
<code>clickCoordinates()</code>	Get the coordinates, in map units, under mouse click
<code>dev()</code>	Specify which device to plot on, making a non-RStudio one as default
<code>newPlot()</code>	Open a new default plotting device
<code>rePlot()</code>	Re-plots all elements of device for refreshing or moving plot

8 File operations

In addition to R's file operations, we have added several here to aid in bulk loading and saving of files for simulation purposes:

<code>loadFiles()</code>	Load simulation objects according to a file list
<code>rasterToMemory()</code>	Read a raster from file to RAM
<code>saveFiles()</code>	Save simulation objects according to outputs and parameters

9 Sample modules included in package

Several dummy modules are included for testing of functionality. These can be found with `file.path(find.package("SpaDES"), "sampleModules")`.

<code>randomLandscapes</code>	Imports, updates, and plots several raster map layers
<code>caribouMovement</code>	A simple agent-based (a.k.a., individual-based) model
<code>fireSpread</code>	A simple model of a spatial spread process

10 Package options

SpaDES packages use the following `options()` to configure behaviour:

- `spades.browserOnError`: If TRUE, the default, then any error rerun the same event with `debugonce` called on it to allow editing to be done. When that browser is continued (e.g., with 'c'), then it will save it reparse it into the `simList` and rerun the edited version. This may allow a `spades` call to be recovered on error, though in many cases that may not be the correct behaviour. For example, if the `simList` gets updated inside that event in an iterative manner, then each run through the event will cause that iteration to occur. When this option is TRUE, then the event will be run at least 3 times: the first time makes the error, the second time has `debugonce` and the third time is after the error is addressed. TRUE is likely somewhat slower.
- `reproducible.cachePath`: The default local directory in which to cache simulation outputs. Default is a temporary directory (typically `/tmp/RtmpXXX/SpaDES/cache`).
- `spades.inputPath`: The default local directory in which to look for simulation inputs. Default is a temporary directory (typically `/tmp/RtmpXXX/SpaDES/inputs`).
- `spades.debug`: The default debugging value `debug` argument in `spades()`. Default is TRUE.
- `spades.lowMemory`: If true, some functions will use more memory efficient (but slower) algorithms. Default FALSE.
- `spades.moduleCodeChecks`: Should the various code checks be run during `simInit`. These are passed to `codetools::checkUsage()`. Default is given by the function, plus these: `list(suppressParamUnused = FALSE, suppressUndefined = TRUE, suppressPartialMatchArgs = FALSE, suppressNoLocalFun = TRUE, skipWith = TRUE)`.
- `spades.modulePath`: The default local directory where modules and data will be downloaded and stored. Default is a temporary directory (typically `/tmp/RtmpXXX/SpaDES/modules`).
- `spades.moduleRepo`: The default GitHub repository to use when downloading modules via `downloadModule`. Default `"PredictiveEcology/SpaDES-modules"`.
- `spades.nCompleted`: The maximum number of completed events to retain in the completed event queue. Default 1000L.
- `spades.outputPath`: The default local directory in which to save simulation outputs. Default is a temporary directory (typically `/tmp/RtmpXXX/SpaDES/outputs`).
- `spades.recoveryMode`: If this a numeric greater than 0 or TRUE, then the discrete event simulator will take a snapshot of the objects in the `simList` that might change (based on metadata `outputObjects` for that module), prior to initiating every event. This will allow the user to be able to recover in case of an error or manual interruption (e.g., Esc). If this is numeric, a copy of that number of "most recent events" will be maintained so that the user can recover and restart more than one event in the past, i.e., redo some of the "completed" events. Default is TRUE, i.e., it will keep the state of the `simList` at the start of the current event. This can be recovered with `restartSpades` and the differences can be seen in a hidden object in the stashed `simList`. There is a message which describes how to find that.
- `spades.switchPkgNamespaces`: Should the search path be modified to ensure a module's required packages are listed first? Default FALSE to keep computational overhead down. If TRUE, there should be no name conflicts among package objects, but it is much slower, especially if the events are themselves fast.
- `spades.tolerance`: The default tolerance value used for floating point number comparisons. Default `.Machine$double.eps^0.5`.

- `spades.useragent`: The default user agent to use for downloading modules from GitHub.com. Default "`https://github.com/PredictiveEcology/SpaDES`".

`.addChangedAttr,simList-method`
.addChangedAttr for simList objects

Description

This will evaluate which elements in the `simList` object changed following this `Cached` function call. It will add a named character string as an attribute `attr(x, ".Cache")$changed`, indicating which ones changed. When this function is subsequently called again, only these changed objects will be returned. All other `simList` objects will remain unchanged.

Usage

```
## S4 method for signature 'simList'
.addChangedAttr(object, preDigest, origArguments, ...)
```

Arguments

<code>object</code>	Any R object returned from a function
<code>preDigest</code>	The full, element by element hash of the input arguments to that same function, e.g., from <code>.robustDigest</code>
<code>origArguments</code>	These are the actual arguments (i.e., the values, not the names) that were the source for <code>preDigest</code>
<code>...</code>	Anything passed to methods.

Value

returns the object with attribute added

See Also

[reproducible::addChangedAttr](#)

.addTagsToOutput,simList-method

.addTagsToOutput for simList objects

Description

See [reproducible::.addTagsToOutput\(\)](#).

Usage

```
## S4 method for signature 'simList'
.addTagsToOutput(object, outputObjects, FUN, preDigestByClass)
```

Arguments

<code>object</code>	Any R object returned from a function
<code>outputObjects</code>	Optional character vector indicating which objects to return. This is only relevant for list, environment (or similar) objects
<code>FUN</code>	A function
<code>preDigestByClass</code>	A list, usually from <code>.preDigestByClass</code>

Value

modified object, with attributes added

Author(s)

Eliot McIntire

```
.cacheMessage, simList-method
.cacheMessage for simList objects
```

Description

See [reproducible::.cacheMessage\(\)](#).

Usage

```
## S4 method for signature 'simList'
.cacheMessage(
  object,
  functionName,
  fromMemoise = getOption("reproducible.useMemoise", TRUE),
  verbose = getOption("reproducible.verbose")
)
```

Arguments

<code>object</code>	Any R object returned from a function
<code>functionName</code>	A character string indicating the function name
<code>fromMemoise</code>	Logical. If TRUE, the message will be about recovery from memoised copy
<code>verbose</code>	Numeric, -1 silent (where possible), 0 being very quiet, 1 showing more messaging, 2 being more messaging, etc. Default is 1. Above 3 will output much more information about the internals of Caching, which may help diagnose Caching challenges. Can set globally with an option, e.g., <code>options('reproducible.verbose' = 0)</code> to reduce t

See Also

[reproducible::.cacheMessage](#)

```
.checkCacheRepo, list-method
.checkCacheRepo for simList objects
```

Description

See [reproducible::.checkCacheRepo\(\)](#).

Usage

```
## S4 method for signature 'list'
.checkCacheRepo(object, create = FALSE)
```

Arguments

object	Any R object returned from a function
create	Logical. If TRUE, then it will create the path for cache.

Value

character string representing a directory path to the cache repo

See Also

[reproducible:::checkCacheRepo](#)

.fileExtensions	<i>File extensions map</i>
-----------------	----------------------------

Description

How to load various types of files in R.

This function has two roles:

1. to proceed with the loading of files that are in a `simList`; or
2. as a shortcut to `simInit(inputs = filelist)`.

A data.frame with information on how to load various types of files in R, containing the columns:

- `exts`: the file extension;
- `fun`: the function to use for files with this file extension;
- `package`: the package from which to load fun.

Usage

```
.fileExtensions()

loadFiles(sim, filelist, ...)

## S4 method for signature 'simList,missing'
loadFiles(sim, filelist, ...)

## S4 method for signature 'missing,ANY'
loadFiles(sim, filelist, ...)

## S4 method for signature 'missing,missing'
loadFiles(sim, filelist, ...)

.saveFileExtensions()
```

Arguments

<code>sim</code>	<code>simList</code> object.
<code>filelist</code>	list or <code>data.frame</code> to call <code>loadFiles</code> directly from the <code>filelist</code> as described in Details
<code>...</code>	Additional arguments.

Value

`data.frame` of file extension, package, and function mappings
the modified `sim`, invisibly.
`data.frame`

Note

Generally not intended to be used by users.

Author(s)

Eliot McIntire and Alex Chubaty

[inputs\(\)](#)

Examples

```
library(SpaDES.core)

# Load random maps included with package
filelist <- data.frame(
  files = dir(getMapPath(tempdir()), full.names = TRUE),
  functions = "rasterToMemory",
  package = "SpaDES.core"
)
sim1 <- loadFiles(filelist = filelist) # loads all the maps to sim1 simList

# Second, more sophisticated. All maps loaded at time = 0, and the last one is reloaded
# at time = 10 and 20 (via "intervals").
# Also, pass the single argument as a list to all functions...
# specifically, when add "native = TRUE" as an argument to the raster function
files <- dir(getMapPath(tempdir()), full.names = TRUE)
arguments <- I(rep(list(lyrs = 1), length(files)))
filelist <- data.frame(
  files = files,
  functions = "terra::rast",
  objectName = NA,
  arguments = arguments,
  loadTime = 0,
  intervals = c(rep(NA, length(files)-1), 10)
)
```

```

sim2 <- loadFiles(filelist = filelist) # only does the time = 0 loading; see next
end(sim2) <- 10
sim2 <- spades(sim2) # loads the object at time 10

# if we extend the end time and continue running, it will load an object scheduled
# at time = 10, and it will also schedule a new object loading at 20 because
# interval = 10
end(sim2) <- 20
sim2 <- spades(sim2) # loads the percentPine map 2 more times, once at 10, once at 20

```

.findSimList	<i>Find simList in a nested list</i>
--------------	--------------------------------------

Description

This is recursive, so it will find the all simLists even if they are deeply nested.

Usage

```
.findSimList(x)
```

Arguments

x	any object, used here only when it is a list with at least one simList in it
---	--

.guessPkgFun	<i>Guess package of a function</i>
--------------	------------------------------------

Description

Guess package of a function

Usage

```
.guessPkgFun(bsf)
```

Arguments

bsf	character. A function name
-----	----------------------------

Value

character. The package and function name as "pkg: :bsf"

`.parseElems, simList-method`
.parseElems for simList class objects

Description

See [quickPlot::.parseElems\(\)](#).

Usage

```
## S4 method for signature 'simList'
.parseElems(tmp, elems, envir)
```

Arguments

<code>tmp</code>	A evaluated object
<code>elems</code>	A character string to be parsed
<code>envir</code>	An environment

Value

An object, parsed from a character string and an environment.

See Also

[quickPlot::.parseElems](#)

`.preDigestByClass, simList-method`
Pre-digesting method for simList

Description

Takes a snapshot of `simList` objects.

Usage

```
## S4 method for signature 'simList'
.preDigestByClass(object)
```

Arguments

<code>object</code>	Any R object returned from a function
---------------------	---------------------------------------

Details

See [reproducible::.preDigestByClass\(\)](#).

Value

character vector corresponding to the names of objects stored in the `.xData` slot

Author(s)

Eliot McIntire

See Also

[reproducible::.preDigestByClass](#)

`.prepareOutput,simList-method`

.prepareOutput for simList objects

Description

See [reproducible::.prepareOutput\(\)](#).

Usage

```
## S4 method for signature 'simList'
.prepareOutput(object, cachePath, ...)
```

Arguments

<code>object</code>	Any R object returned from a function
<code>cachePath</code>	A repository used for storing cached objects. This is optional if <code>Cache</code> is used inside a <code>SpaDES</code> module.
<code>...</code>	Anything passed to methods.

Value

the modified object

See Also

[reproducible::.prepareOutput](#)

<code>.quickCheck</code>	<i>The SpaDES.core variable to switch between quick and robust checking</i>
--------------------------	---

Description

A variable that can be use by module developers and model users to switch between a quick check of functions like `downloadData`, `Cache`. The module developer must actually use this in their code.

Usage

```
.quickCheck
```

Format

An object of class `logical` of length 1.

<code>.rndstr</code>	<i>Generate random strings</i>
----------------------	--------------------------------

Description

Generate a vector of random alphanumeric strings each of an arbitrary length.

Usage

```
.rndstr(n = 1, len = 8)  
  
rndstr(n, len, characterFirst)  
  
## S4 method for signature 'numeric,numeric,logical'  
rndstr(n, len, characterFirst)  
  
## S4 method for signature 'numeric,numeric,missing'  
rndstr(n, len)  
  
## S4 method for signature 'numeric,missing,logical'  
rndstr(n, characterFirst)  
  
## S4 method for signature 'missing,numeric,logical'  
rndstr(len, characterFirst)  
  
## S4 method for signature 'numeric,missing,missing'  
rndstr(n)
```

```
## S4 method for signature 'missing,numeric,missing'
rndstr(len)

## S4 method for signature 'missing,missing,logical'
rndstr(characterFirst)

## S4 method for signature 'missing,missing,missing'
rndstr(n, len, characterFirst)
```

Arguments

<code>n</code>	Number of strings to generate (default 1). Will attempt to coerce to integer value.
<code>len</code>	Length of strings to generate (default 8). Will attempt to coerce to integer value.
<code>characterFirst</code>	Logical, if TRUE, then a letter will be the first character of the string (useful if being used for object names).

Value

Character vector of random strings.

Author(s)

Alex Chubaty and Eliot McIntire

Examples

```
set.seed(11)
rndstr()
rndstr(len = 10)
rndstr(characterFirst = FALSE)
rndstr(n = 5, len = 10)
rndstr(n = 5)
rndstr(n = 5, characterFirst = TRUE)
rndstr(len = 10, characterFirst = TRUE)
rndstr(n = 5, len = 10, characterFirst = TRUE)
```

.robustDigest,simList-method

.robustDigest for simList objects

Description

This is intended to be used within the `Cache` function, but can be used to evaluate what a `simList` would look like once it is converted to a repeatably digestible object.

Usage

```
## S4 method for signature 'simList'
.robustDigest(object, .objects, length, algo, quick, classOptions)
```

Arguments

<code>object</code>	an object to digest.
<code>.objects</code>	Character vector of objects to be digested. This is only applicable if there is a list, environment (or similar) with named objects within it. Only this/these objects will be considered for caching, i.e., only use a subset of the list, environment or similar objects. In the case of nested list-type objects, this will only be applied outermost first.
<code>length</code>	Numeric. If the element passed to <code>Cache</code> is a <code>Path</code> class object (from e.g., <code>asPath(filename)</code>) or it is a <code>Raster</code> with file-backing, then this will be passed to <code>digest::digest</code> , essentially limiting the number of bytes to digest (for speed). This will only be used if <code>quick = FALSE</code> . Default is <code>getOption("reproducible.length")</code> , which is set to <code>Inf</code> .
<code>algo</code>	The algorithms to be used; currently available choices are <code>md5</code> , which is also the default, <code>sha1</code> , <code>crc32</code> , <code>sha256</code> , <code>sha512</code> , <code>xxhash32</code> , <code>xxhash64</code> , <code>murmur32</code> , <code>spookyhash</code> , <code>blake3</code> , <code>crc32c</code> , <code>xxh3_64</code> , and <code>xxh3_128</code> .
<code>quick</code>	Logical or character. If <code>TRUE</code> , no disk-based information will be assessed, i.e., only memory content. See Details section about <code>quick</code> in Cache() .
<code>classOptions</code>	Optional list. This will pass into <code>.robustDigest</code> for specific classes. Should be options that the <code>.robustDigest</code> knows what to do with.

Details

See [reproducible::.robustDigest\(\)](#). This method strips out stuff from a `simList` class object that would make it otherwise not reproducibly digestible between sessions, operating systems, or machines. This will likely still not allow identical digest results across R versions.

Author(s)

Eliot McIntire

See Also

[reproducible::.robustDigest\(\)](#)

```
.tagsByClass,simList-method
      .tagsByClass for simList objects
```

Description

See [reproducible::.tagsByClass\(\)](#). Adds current moduleName, eventType, eventTime, and function:spades as userTags.

Usage

```
## S4 method for signature 'simList'
.tagsByClass(object)
```

Arguments

object Any R object returned from a function

Author(s)

Eliot McIntire

See Also

[reproducible::.tagsByClass](#)

```
.wrap.simList                    Methods for .wrap and .unwrap
```

Description

Methods for .wrap and .unwrap

Usage

```
## S3 method for class 'simList'
.wrap(
  obj,
  cachePath,
  preDigest,
  drv = getOption("reproducible.drv", NULL),
  conn = getOption("reproducible.conn", NULL),
  verbose = getOption("reproducible.verbose"),
  outputObjects = NULL,
  ...
)
```

```
## S3 method for class 'simList'
.unwrap(
  obj,
  cachePath,
  cacheId,
  drv = getOption("reproducible.drv", NULL),
  conn = getOption("reproducible.conn", NULL),
  ...
)
```

Arguments

<code>obj</code>	Any arbitrary R object.
<code>cachePath</code>	A repository used for storing cached objects. This is optional if <code>Cache</code> is used inside a <code>SpaDES</code> module.
<code>preDigest</code>	The list of <code>preDigest</code> that comes from <code>CacheDigest</code> of an object
<code>drv</code>	an object that inherits from <code>DBIDriver</code> , or an existing <code>DBIConnection</code> object (in order to clone an existing connection).
<code>conn</code>	A <code>DBIConnection</code> object, as returned by <code>dbConnect()</code> .
<code>verbose</code>	Numeric, -1 silent (where possible), 0 being very quiet, 1 showing more messaging, 2 being more messaging, etc. Default is 1. Above 3 will output much more information about the internals of <code>Caching</code> , which may help diagnose <code>Caching</code> challenges. Can set globally with an option, e.g., <code>options('reproducible.verbose' = 0)</code> to reduce t
<code>outputObjects</code>	Optional character vector indicating which objects to return. This is only relevant for list, environment (or similar) objects
<code>...</code>	Other arguments. Can be in the form of <code>tagKey = tagValue</code> , such as, <code>class = "numeric"</code> to find all entries that are numerics in the cache. Note: the special cases of <code>cacheId</code> and <code>fun</code> have their own named arguments in these functions. Also can be <code>regexp = xx</code> , where <code>xx</code> is <code>TRUE</code> if the user is passing a regular expression. Otherwise, <code>userTags</code> will need to be exact matches. Default is missing, which is the same as <code>TRUE</code> . If there are errors due to regular expression problem, try <code>FALSE</code> . For <code>cc</code> , it is passed to <code>clearCache</code> , e.g., <code>ask</code> , <code>userTags</code> . For <code>showCache</code> , it can also be <code>sorted = FALSE</code> to return the object unsorted.
<code>cacheId</code>	An optional character vector describing the <code>cacheIds</code> to extract. Only entries with this/these <code>cacheIds</code> will be returned. If <code>useDBI(FALSE)</code> , this will also be dramatically faster than using <code>userTags</code> , for a large cache.

Value

The same object as passed into the function, but dealt with so that it can be saved to disk.

all.equal.simList	<i>All equal method for simList objects</i>
-------------------	---

Description

This function removes a few attributes that are added internally by **SpaDES.core** and are not relevant to the `all.equal`. One key element removed is any time stamps, as these are guaranteed to be different. A possibly very important argument to pass to the `...` is `check.attributes = FALSE` which will allow successful comparisons of many objects that might have pointers.

Usage

```
## S3 method for class 'equal.simList'
all(target, current, ...)
```

Arguments

target	R object.
current	other R object, to be compared with target.
...	further arguments for different methods, notably the following two, for numerical comparison:

Value

See [base::all.equal\(\)](#)

anyPlotting	<i>Test whether there should be any plotting from .plots module parameter</i>
-------------	---

Description

This will do all the various tests needed to determine whether plotting of one sort or another will occur. Testing any of the types as listed in [Plots\(\)](#) argument types. Only the first 3 letters of the type are required.

Usage

```
anyPlotting(.plots)
```

Arguments

.plots	Usually will be the <code>P(sim)\$plots</code> is used within a module.
--------	---

Value

logical of length 1

append_attr	<i>Append attributes</i>
-------------	--------------------------

Description

Ordinary base lists and vectors do not retain their attributes when subsetting or appending. This function appends items to a list while preserving the attributes of items in the list (but not of the list itself).

Usage

```
append_attr(x, y)

## S4 method for signature 'list,list'
append_attr(x, y)
```

Arguments

`x, y` A list of items with optional attributes.

Details

Similar to `updateList` but does not require named lists.

Value

An updated list with attributes.

Author(s)

Alex Chubaty and Eliot McIntire

Examples

```
tmp1 <- list("apple", "banana")
tmp1 <- lapply(tmp1, `attributes<-`, list(type = "fruit"))
tmp2 <- list("carrot")
tmp2 <- lapply(tmp2, `attributes<-`, list(type = "vegetable"))
append_attr(tmp1, tmp2)
rm(tmp1, tmp2)
```

bindrows	<i>Simple wrapper around data.table::rbindlist</i>
----------	--

Description

This simply sets defaults to fill = TRUE, and use.names = TRUE.

Usage

```
bindrows(...)
```

Arguments

... one or more data.frame, data.table, or list objects

Value

a data.table object

checkModule	<i>Check for the existence of a remote module</i>
-------------	---

Description

Looks in the remote repo for a module named name.

Usage

```
checkModule(name, repo)
```

```
## S4 method for signature 'character,character'
checkModule(name, repo)
```

```
## S4 method for signature 'character,missing'
checkModule(name)
```

Arguments

name	Character string giving the module name.
repo	GitHub repository name. Default is "PredictiveEcology/SpaDES-modules", which is specified by the global option spades.moduleRepo.

Value

a character vector of module file paths (invisibly).

Author(s)

Eliot McIntire and Alex Chubaty

checkModuleLocal	<i>Check for the existence of a module locally</i>
------------------	--

Description

Looks the module path for a module named name, and checks for existence of all essential module files listed below.

Usage

```
checkModuleLocal(name, path, version)

## S4 method for signature 'character,character,character'
checkModuleLocal(name, path, version)

## S4 method for signature 'character,ANY,ANY'
checkModuleLocal(name, path, version)
```

Arguments

name	Character string giving the module name.
path	Local path to modules directory. Default is specified by the global option <code>spades.modulePath</code> .
version	Character specifying the desired module version.

Details

- 'data/CHECKSUMS.txt'
- 'name.R'

Value

Logical indicating presence of the module (invisibly).

Author(s)

Alex Chubaty

checkObject	<i>Check for existence of object(s) referenced by a objects slot of a simList object</i>
-------------	--

Description

Check that a named object exists in the provide simList environment slot, and optionally has desired attributes.

Usage

```
checkObject(sim, name, object, layer, ...)  
  
## S4 method for signature 'simList,ANY,ANY'  
checkObject(sim, name, object, layer, ...)  
  
## S4 method for signature 'simList,character,missing'  
checkObject(sim, name, object, layer, ...)  
  
## S4 method for signature 'missing,ANY,ANY'  
checkObject(sim, name, object, layer, ...)
```

Arguments

sim	A simList() object.
name	A character string specifying the name of an object to be checked.
object	An object. This is mostly used internally, or with layer, because it will fail if the object does not exist.
layer	Character string, specifying a layer name in a Raster, if the name is a Raster* object.
...	Additional arguments. Not implemented.

Value

Invisibly return TRUE indicating object exists; FALSE if not.

Author(s)

Alex Chubaty and Eliot McIntire

See Also

[library\(\)](#).

Examples

```

sim <- simInit()
sim$a <- 1
sim$b <- list(d = 1)
sim$r <- terra::rast(terra::ext(0,2,0,2), res = 1, vals = 2)
sim$s <- c(sim$r, terra::rast(terra::ext(0,2,0,2), res = 1, vals = 3))
names(sim$s) <- c("r1", "r2") # give layer names
(checkObject(sim, name = "a")) # TRUE
(checkObject(sim, name = "b", layer = "d")) # TRUE
(checkObject(sim, name = "d")) # FALSE
(checkObject(sim, name = "r")) # TRUE
(checkObject(sim, object = sim$s)) # TRUE
(checkObject(sim, object = sim$s, layer = "r1")) # TRUE

```

checkParams

Check use and existence of parameters passed to simulation.

Description

Checks that all parameters passed are used in a module, and that all parameters used in a module are passed.

Usage

```

checkParams(sim, coreParams, ...)

## S4 method for signature 'simList,list'
checkParams(sim, coreParams, ...)

```

Arguments

sim	A simList simulation object.
coreParams	List of default core parameters.
...	Additional arguments. Not implemented.

Value

Invisibly return TRUE indicating object exists; FALSE if not. Sensible messages are produced identifying missing parameters.

Author(s)

Alex Chubaty

checkpointFile	<i>Simulation checkpoints</i>
----------------	-------------------------------

Description

Save and reload the current state of the simulation, including the state of the random number generator, by scheduling checkpoint events.

Usage

```
checkpointFile(sim)

## S4 method for signature 'simList'
checkpointFile(sim)

checkpointFile(sim) <- value

## S4 replacement method for signature 'simList'
checkpointFile(sim) <- value

checkpointInterval(sim)

## S4 method for signature 'simList'
checkpointInterval(sim)

checkpointInterval(sim) <- value

## S4 replacement method for signature 'simList'
checkpointInterval(sim) <- value

doEvent.checkpoint(sim, eventTime, eventType, debug = FALSE)

checkpointLoad(file)

.checkpointSave(sim, file)
```

Arguments

sim	A simList simulation object.
value	The parameter value to be set (in the corresponding module and param).
eventTime	A numeric specifying the time of the next event.
eventType	A character string specifying the type of event: one of either "init", "load", or "save".
debug	Optional logical flag determines whether sim debug info will be printed (default debug = FALSE).
file	The checkpoint file.

Value

Returns the modified `simList` object.

Note

Checkpoint files are intended to be used locally, and do not invoke the simulation archiving tools to bundle and subsequently extract simulation files (e.g., file-backed rasters).

RNG save code adapted from: http://www.cookbook-r.com/Numbers/Saving_the_state_of_the_random_number_generator/ and <https://stackoverflow.com/q/13997444/1380598>

Author(s)

Alex Chubaty

See Also

[.Random.seed](#).

Other functions to access elements of a 'simList' object: [.addDepends\(\)](#), [envir\(\)](#), [events\(\)](#), [globals\(\)](#), [inputs\(\)](#), [modules\(\)](#), [objs\(\)](#), [packages\(\)](#), [params\(\)](#), [paths\(\)](#), [progressInterval\(\)](#), [times\(\)](#)

checksums

Calculate checksum for a module's data files

Description

Verify (and optionally write) checksums for data files in a module's 'data/' subdirectory. The file 'data/CHECKSUMS.txt' contains the expected checksums for each data file. Checksums are computed using `reproducible::digest`, which is simply a wrapper around `digest::digest`.

Usage

```
checksums(module, path, ...)
```

Arguments

<code>module</code>	Character string giving the name of the module.
<code>path</code>	Character string giving the path to the module directory.
<code>...</code>	Passed to reproducible::Checksums() , notably, <code>write</code> , <code>quickCheck</code> , <code>checksumFile</code> and <code>files</code> .

Details

Modules may require data that for various reasons cannot be distributed with the module source code. In these cases, the module developer should ensure that the module downloads and extracts the data required. It is useful to not only check that the data files exist locally but that their checksums match those expected.

Note

In version 1.2.0 and earlier, two checksums per file were required because of differences in the checksum hash values on Windows and Unix-like platforms. Recent versions use a different (faster) algorithm and only require one checksum value per file. To update your 'CHECKSUMS.txt' files using the new algorithm:

1. specify your module (`moduleName <- "my_module"`);
2. use a temporary location to ensure all modules get fresh copies of the data (`tmpdir <- file.path(tempdir(), "SpaDES_modules")`);
3. download your module's data to the temp dir (`downloadData(moduleName, tmpdir)`);
4. initialize a dummy simulation to ensure any 'data prep' steps in the .inputObjects section are run (`simInit(modules = moduleName)`);
5. recalculate your checksums and overwrite the file (`checksums(moduleName, tmpdir, write = TRUE)`);
6. copy the new checksums file to your working module directory (the one not in the temp dir) (`file.copy(from = file.path(tmpdir, moduleName, 'data', 'CHECKSUMS.txt'), to = file.path('path/to/moduleName', 'data', 'CHECKSUMS.txt'), overwrite = TRUE)`).

citation

A citation method for SpaDES modules

Description

This is a wrapper around `utils::citation()` for cases with `package` is a character string. Otherwise, it takes a `simList`.

Usage

```
citation(package, lib.loc = NULL, auto = NULL, module = character())

## S4 method for signature 'simList'
citation(package, lib.loc = NULL, auto = NULL, module = character())

## S4 method for signature 'character'
citation(package, lib.loc = NULL, auto = NULL, module = character())
```

Arguments

<code>package</code>	For compatibility with <code>utils::citation()</code> . This can be a <code>simList</code> or a character string for a package name.
<code>lib.loc</code>	a character vector with path names of R libraries, or the directory containing the source for package, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

auto	a logical indicating whether the default citation auto-generated from the package 'DESCRIPTION' metadata should be used or not, or NULL (default), indicating that a 'CITATION' file is used if it exists, or an object of class " packageDescription " with package metadata (see below).
module	Optional character string indicating which module params should come from.

Value

The citation information for a SpaDES module.

classFilter	<i>Filter objects by class</i>
-------------	--------------------------------

Description

Based on <https://stackoverflow.com/a/5158978/1380598>.

Usage

```
classFilter(x, include, exclude, envir)

## S4 method for signature 'character,character,character,environment'
classFilter(x, include, exclude, envir)

## S4 method for signature 'character,character,character,missing'
classFilter(x, include, exclude)

## S4 method for signature 'character,character,missing,environment'
classFilter(x, include, envir)

## S4 method for signature 'character,character,missing,missing'
classFilter(x, include)
```

Arguments

x	Character vector of object names to filter, possibly from ls.
include	Class(es) to include, as a character vector.
exclude	Optional class(es) to exclude, as a character vector.
envir	The environment ins which to search for objects. Default is the calling environment.

Value

Vector of object names matching the class filter.

Note

`inherits()` is used internally to check the object class, which can, in some cases, return results inconsistent with `is`. See <https://stackoverflow.com/a/27923346/1380598>. These (known) cases are checked manually and corrected.

Author(s)

Alex Chubaty

Examples

```
## from local (e.g., function) environment
local({
  e <- environment()
  a <- list(1:10)      # class `list`
  b <- letters         # class `character`
  d <- stats::runif(10) # class `numeric`
  f <- sample(1L:10L) # class `numeric`, `integer`
  g <- lm( jitter(d) ~ d ) # class `lm`
  h <- glm( jitter(d) ~ d ) # class `lm`, `glm`
  classFilter(ls(), include=c("character", "list"), envir = e)
  classFilter(ls(), include = "numeric", envir = e)
  classFilter(ls(), include = "numeric", exclude = "integer", envir = e)
  classFilter(ls(), include = "lm", envir = e)
  classFilter(ls(), include = "lm", exclude = "glm", envir = e)
  rm(a, b, d, e, f, g, h)
})

## from another environment (can be omitted if .GlobalEnv)
e = new.env(parent = emptyenv())
e$a <- list(1:10)      # class `list`
e$b <- letters         # class `character`
e$d <- stats::runif(10) # class `numeric`
e$f <- sample(1L:10L) # class `numeric`, `integer`
e$g <- lm( jitter(e$d) ~ e$d ) # class `lm`
e$h <- glm( jitter(e$d) ~ e$d ) # class `lm`, `glm`
classFilter(ls(e), include=c("character", "list"), envir = e)
classFilter(ls(e), include = "numeric", envir = e)
classFilter(ls(e), include = "numeric", exclude = "integer", envir = e)
classFilter(ls(e), include = "lm", envir = e)
classFilter(ls(e), include = "lm", exclude = "glm", envir = e)
rm(a, b, d, f, g, h, envir = e)
rm(e)
```

clearCache,simList-method

clearCache for simList objects

Description

This will take the cachePath(object) and pass

Usage

```
## S4 method for signature 'simList'
clearCache(
  x,
  userTags = character(),
  after = NULL,
  before = NULL,
  fun = NULL,
  cacheId = NULL,
  ask = getOption("reproducible.ask"),
  useCloud = FALSE,
  cloudFolderID = getOption("reproducible.cloudFolderID", NULL),
  drv = getDrv(getOption("reproducible.drv", NULL)),
  conn = getOption("reproducible.conn", NULL),
  verbose = getOption("reproducible.verbose"),
  ...
)

## S4 method for signature 'simList'
showCache(
  x,
  userTags = character(),
  after = NULL,
  before = NULL,
  fun = NULL,
  cacheId = NULL,
  drv = getDrv(getOption("reproducible.drv", NULL)),
  conn = getOption("reproducible.conn", NULL),
  verbose = getOption("reproducible.verbose"),
  ...
)

## S4 method for signature 'simList'
keepCache(
  x,
  userTags = character(),
  after = NULL,
  before = NULL,
  ask = getOption("reproducible.ask"),
  drv = getDrv(getOption("reproducible.drv", NULL)),
  conn = getOption("reproducible.conn", NULL),
  verbose = getOption("reproducible.verbose"),
  ...
)
```

Arguments

<code>x</code>	A <code>simList</code> or a directory containing a valid Cache repository. Note: For compatibility with <code>Cache</code> argument, <code>cachePath</code> can also be used instead of <code>x</code> , though <code>x</code> will take precedence.
<code>userTags</code>	Character vector. If used, this will be used in place of the <code>after</code> and <code>before</code> . Specifying one or more <code>userTag</code> here will clear all objects that match those tags. Matching is via regular expression, meaning partial matches will work unless strict beginning (^) and end (\$) of string characters are used. Matching will be against any of the 3 columns returned by <code>showCache()</code> , i.e., <code>artifact</code> , <code>tagValue</code> or <code>tagName</code> . Also, if <code>length(userTags) > 1</code> , then matching is by and. For or matching, use <code> </code> in a single character string. See examples.
<code>after</code>	A time (POSIX, character understandable by <code>data.table</code>). Objects cached after this time will be shown or deleted.
<code>before</code>	A time (POSIX, character understandable by <code>data.table</code>). Objects cached before this time will be shown or deleted.
<code>fun</code>	An optional character vector describing the function name to extract. Only functions with this/these functions will be returned.
<code>cacheId</code>	An optional character vector describing the <code>cacheIds</code> to extract. Only entries with this/these <code>cacheIds</code> will be returned. If <code>useDBI(FALSE)</code> , this will also be dramatically faster than using <code>userTags</code> , for a large cache.
<code>ask</code>	Logical. If <code>FALSE</code> , then it will not ask to confirm deletions using <code>clearCache</code> or <code>keepCache</code> . Default is <code>TRUE</code>
<code>useCloud</code>	Logical. If <code>TRUE</code> , then every object that is deleted locally will also be deleted in the <code>cloudFolderID</code> , if it is non-NULL
<code>cloudFolderID</code>	A googledrive dribble of a folder, e.g., using <code>drive_mkdir()</code> . If left as <code>NULL</code> , the function will create a cloud folder with name from last two folder levels of the <code>cachePath</code> path, : <code>paste0(basename(dirname(cachePath)), "_", basename(cachePath))</code> . This <code>cloudFolderID</code> will be added to <code>options("reproducible.cloudFolderID")</code> but this will not persist across sessions. If this is a character string, it will treat this as a folder name to create or use on GoogleDrive.
<code>drv</code>	an object that inherits from <code>DBIDriver</code> , or an existing <code>DBIConnection</code> object (in order to clone an existing connection).
<code>conn</code>	A <code>DBIConnection</code> object, as returned by <code>dbConnect()</code> .
<code>verbose</code>	Numeric, -1 silent (where possible), 0 being very quiet, 1 showing more messaging, 2 being more messaging, etc. Default is 1. Above 3 will output much more information about the internals of Caching, which may help diagnose Caching challenges. Can set globally with an option, e.g., <code>options('reproducible.verbose' = 0)</code> to reduce t
<code>...</code>	Other arguments. Can be in the form of <code>tagKey = tagValue</code> , such as, <code>class = "numeric"</code> to find all entries that are numerics in the cache. Note: the special cases of <code>cacheId</code> and <code>fun</code> have their own named arguments in these functions. Also can be <code>regex = xx</code> , where <code>xx</code> is <code>TRUE</code> if the user is passing a regular expression. Otherwise, <code>userTags</code> will need to be exact matches. Default is missing, which is the same as <code>TRUE</code> . If there are errors due to regular expression problem, try <code>FALSE</code> . For <code>cc</code> , it is passed to <code>clearCache</code> , e.g., <code>ask</code> , <code>userTags</code> . For <code>showCache</code> , it can also be <code>sorted = FALSE</code> to return the object unsorted.

Value

A `data.table` object showing the subset of items in the cache, located at `cachePath` of the `sim` object, if `sim` is provided, or located in `cachePath`. For `clearCache` (invoked for its side effect of clearing objects matching `userTags`, or those between `after` or `before`), the returned `data.table` shows the removed items (invisibly).

<code>convertToPackage</code>	<i>Convert standard module code into an R package</i>
-------------------------------	---

Description

EXPERIMENTAL – USE WITH CAUTION. This function attempts to convert a SpaDES module to the closest rendition of the same functionality, but in an R package. The main change is that instead of SpaDES `core` parsing the functions using custom parsing tools, it will use `pkgload::load_all` on the package functions. These

Usage

```
convertToPackage(
  module = NULL,
  path = getOption("spades.modulePath"),
  buildDocuments = TRUE
)
```

Arguments

<code>module</code>	Character string of module name, without path
<code>path</code>	Character string of <code>modulePath</code> . Defaults to <code>getOption("spades.modulePath")</code> .
<code>buildDocuments</code>	A logical. If <code>TRUE</code> , the default, then the documentation will be built, if any exists, using <code>roxygen2::roxygenise</code> .

Details

`convertToPackage` will:

1. move any functions that were defined within the main module file (`moduleName.R`) into the `R` folder, with the same name, but ending with `Fns.R`;
2. keep the `defineModule(...)` function call with all the metadata in the same file, `moduleName.R`, but with all other content removed, i.e., only the `defineModule(...)` will be here.
3. build documentation from all the **roxygen2** tags
4. places one **roxygen2** tag, `@export` in front of the `doEvent.moduleName` function, so that the function can be found by SpaDES `core`
5. All other functions will be kept "private", i.e., not exported, unless the user manually adds `@export`, as per a normal package
6. will make a `DESCRIPTION` file from the SpaDES module metadata

7. will make a NAMESPACE file from the **roxygen2** tags (e.g., @export)

A user can continue to use the module code as before, i.e., by editing it and putting `browser()` etc. It will be parsed during `simInit`. Because the functions are "in a package", they are automatically namespaced with each other, so that when you want to use a function from that package, there is no need to put a prefix with the package name.

This function does not install anything (e.g., `devtools::install`). After running this function, `simInit` will automatically detect that this is now a package and will load the functions (via `pkgload::load_all`) from the source files. This will have the effect that it emulates the "non-package" behaviour of a SpaDES module exactly. After running this function, current tests show no impact on module behaviour, other than event-level and module-level Caching will show changes and will be rerun. Function-level Caching appears unaffected. In other words, this should cause no changes to running the module code via `simInit` and `spades`.

This function will create and fill a minimal DESCRIPTION file. This will leave the `defineModule` function call as the only code in the main module file. This `defineModule` and a `doEvent.xxx` are the only 2 elements that are required for an R package to be considered a SpaDES module. With these changes, the module should still function normally, but will be able to act like an R package, e.g., for writing function documentation with `roxygen2`, using the `testthat` infrastructure, etc.

This function is intended to be run once for a module that was created using the "standard" SpaDES module structure (e.g., from a `newModule` call). There is currently no way to "revert" the changes from R (though it can be done using version control utilities if all files are under version control, e.g., GitHub). Currently `SpaDES.core` identifies a module as being a package if it has a DESCRIPTION file, or if it has been installed to the `.libPaths()` e.g., via `devtools::install` or the like. So one can simply remove the package from `.libPaths` and delete the DESCRIPTION file and `SpaDES.core` will treat it as a normal module.

Value

Invoked for its side effects. There will be a new or modified DESCRIPTION file in the root directory of the module. Any functions that were in the main module script (i.e., the .R file whose filename is the name of the module and is in the root directory of the module) will be moved to individual .R files in the R folder. Any function with a dot prefix will have the dot removed in its respective filename, but the function name is unaffected.

Currently, `SpaDES.core` does not install the package under any circumstances. It will load it via `pkgdown::load_all`, and optionally (`option("spades.moduleDocument" = TRUE)`) build documentation via `roxygen2::roxygenise` within the `simInit` call. This means that any modifications to source code will be read in during the `simInit` call, as is the practice when a module is not a package.

invoked for the side effect of converting a module to a package

Reverting

Currently, this is not a reversible process. We recommend trying one module at a time, running your code. If all seems to work, then great. Commit the changes. If things don't seem to work, then revert the changes and continue on as before. Ideally, file a bug report on the `SpaDES.core` GitHub.com pages.

Currently

Exported functions

The only function that will be exported by default is the `doEvent.xxx`, where `xxx` is the module name. If any other module is to be exported, it must be explicitly exported with e.g., `@export`, and then building the `NAMESPACE` file, e.g., via `devtools::document(moduleRootPath)`. NOTE: as long as all the functions are being used inside each other, and they all can be traced back to a call in `doEvent.xxx`, then there is no need to export anything else.

DESCRIPTION

The `DESCRIPTION` file that is created (destroying any existing `DESCRIPTION` file) with this function will have several elements that a user may wish to change. Notably, all packages that were in `reqdPkgs` in the `SpaDES` module metadata will be in the `Imports` section of the `DESCRIPTION`. To accommodate the need to see these functions, a new R script, `imports.R` will be created with `@import` for each package in `reqdPkgs` of the module metadata. However, if a module already has used `@importFrom` for importing a function from a package, then the generic `@import` will be omitted for that (those) package(s). So, a user should likely follow standard R package best practices and use `@importFrom` to identify the specific functions that are required within external packages, thereby limiting function name collisions (and the warnings that come with them).

Other elements of a standard `DESCRIPTION` file that will be missing or possibly inappropriately short are `Title`, `Description`, `URL`, `BugReports`.

Installing as a package

There is no need to "install" the source code as a package because `simInit` will load it on the fly. But, there may be reasons to install it, e.g., to have access to individual functions, help manual, running tests etc. To do this, simply use the `devtools::install(pathToModuleRoot)`. Even if it is installed, `simInit` will nevertheless run `pkgload::load_all` to ensure the `spades` call will be using the current source code.

Examples

```
if (requireNamespace("ggplot2") && requireNamespace("pkgload")) {
  tmpdir <- tmpdir2()
  newModule("test", tmpdir, open = FALSE)
  convertToPackage("test", path = tmpdir)
  pkgload::load_all(file.path(tmpdir, "test"))
  pkgload::unload("test")
}
```

Copy,simList-method *Copy for simList class objects*

Description

Because a `simList` works with an environment to hold all objects, all objects within that slot are pass-by-reference. That means it is not possible to simply copy an object with an assignment operator: the two objects will share the same objects. As one `simList` object changes so will the other. When this is not the desired behaviour, use this function.

Usage

```
## S4 method for signature 'simList'  
Copy(object, objects, queues, modules, ...)
```

Arguments

object	An R object (likely containing environments) or an environment.
objects	Whether the objects contained within the <code>simList</code> environment should be copied. Default <code>TRUE</code> , which may be slow.
queues	Logical. Should the events queues (events, current, completed) be deep copied via <code>data.table::copy()</code>
modules	Logical. Should list of modules be copied.
...	Only used for custom Methods

Details

`simList` objects can contain a lot of information, much of which could be in pass-by-reference objects (e.g., `data.table` class), and objects that are file-backed, such as some `Raster*`-class objects. For all the objects that are file-backed, it is likely *very* important to give unique file-backed directories. This should be passed here, which gets passed on to the many methods of `Copy` in `reproducible`.

Value

a copy of object

Note

uses capital C, to limit confusion with e.g., `data.table::copy()`.

Author(s)

Eliot McIntire

copyModule	<i>Create a copy of an existing module</i>
------------	--

Description

Create a copy of an existing module

Usage

```
copyModule(from, to, path, ...)

## S4 method for signature 'character,character,character'
copyModule(from, to, path, ...)

## S4 method for signature 'character,character,missing'
copyModule(from, to, path, ...)
```

Arguments

from	The name of the module to copy.
to	The name of the copy.
path	The path to a local module directory. Defaults to the path set by the <code>spades.modulePath</code> option. See setPaths() .
...	Additional arguments to <code>file.copy</code> , e.g., <code>overwrite = TRUE</code> .

Value

Invisible logical indicating success (TRUE) or failure (FALSE).

Author(s)

Alex Chubaty

createsOutput	<i>Define an output object of a module</i>
---------------	--

Description

Used to specify an output object's name, class, description and other specifications.

Usage

```
createsOutput(objectName, objectClass, desc, ...)

## S4 method for signature 'ANY,ANY,ANY'
createsOutput(objectName, objectClass, desc, ...)

## S4 method for signature 'character,character,character'
createsOutput(objectName, objectClass, desc, ...)
```

Arguments

objectName	Character string to define the output object's name.
objectClass	Character string to specify the output object's class.
desc	Text string providing a brief description of the output object. If there are extra spaces or carriage returns, these will be stripped, allowing for multi-line character strings without using paste or multiple quotes.
...	Other specifications of the output object.

Value

A data.frame suitable to be passed to outputObjects in a module's metadata.

Author(s)

Yong Luo

Examples

```
outputObjects <- bindrows(
  createsOutput(objectName = "outputObject1", objectClass = "character",
    desc = "this is for example"),
  createsOutput(objectName = "outputObject2", objectClass = "numeric",
    desc = "this is for example",
    otherInformation = "I am the second output object")
)
```

defineEvent

Alternative way to define events in SpaDES.core

Description

There are two ways to define what occurs during an event: defining a function called `doEvent.moduleName`, where `moduleName` is the actual module name. This approach is the original approach used in `SpaDES.core`, and it must have an explicit switch statement branching on `eventType`. The newer approach (still experimental) uses `defineEvent()`. Instead of creating, `doEvent.moduleName()`, it creates one function for each event, each with the name `doEvent.moduleName.eventName`. This may be a little bit cleaner, but both will still work.

Usage

```
defineEvent(
  sim,
  eventName = "init",
  code,
  moduleName = NULL,
  envir = parent.frame()
)
```

Arguments

<code>sim</code>	A <code>simList</code>
<code>eventName</code>	Character string of the desired event name to define. Default is "init"
<code>code</code>	An expression that defines the code to execute during the event. This will be captured, and pasted into a new function (<code>doEvent.moduleName.eventName</code>), remaining unevaluated until that new function is called.
<code>moduleName</code>	Character string of the name of the module. If this function is used within a module, then it will try to find the module name.
<code>envir</code>	An optional environment to specify where to put the resulting function. The default will place a function called <code>doEvent.moduleName.eventName</code> in the module function location, i.e., <code>sim\$.mods[[moduleName]]</code> . However, if this location does not exist, then it will place it in the <code>parent.frame()</code> , with a message. Normally, especially, if used within SpaDES module code, this should be left missing.

[defineModule\(\)](#), [simInit\(\)](#), [scheduleEvent\(\)](#)

Examples

```
sim <- simInit()

# these put the functions in the parent.frame() which is .GlobalEnv for an interactive user
defineEvent(sim, "init", moduleName = "thisTestModule", code = {
  sim <- Init(sim) # initialize
  # Now schedule some different event for "current time", i.e., will
  #   be put in the event queue to run *after* this current event is finished
  sim <- scheduleEvent(sim, time(sim), "thisTestModule", "grow")
}, envir = envir(sim))

defineEvent(sim, "grow", moduleName = "thisTestModule", code = {
  sim <- grow(sim) # grow
  # Now schedule this same event for "current time plus 1", i.e., a "loop"
  sim <- scheduleEvent(sim, time(sim) + 1, "thisTestModule", "grow") # for "time plus 1"
})

Init <- function(sim) {
  sim$messageToWorld <- "Now the sim has an object in it that can be accessed"
```

```

sim$size <- 1 # initializes the size object --> this can be anything, Raster, list, whatever
message(sim$messageToWorld)
return(sim) # returns all the things you added to sim as they are in the simList
}

grow <- function(sim) {
  sim$size <- sim$size + 1 # increments the size
  message(sim$size)
  return(sim)
}

# schedule that first "init" event
sim <- scheduleEvent(sim, 0, "thisTestModule", "init")
# Look at event queue
events(sim) # shows the "init" we just added

# this is skipped when running in automated tests; it is fine in interactive use
out <- spades(sim)

```

defineModule

Define a new module.

Description

Specify a new module's metadata as well as object and package dependencies. Packages are loaded during this call. Any or all of these can be missing, with missing values set to defaults

Usage

```

defineModule(sim, x)

## S4 method for signature 'simList,list'
defineModule(sim, x)

```

Arguments

sim	A simList object from which to extract element(s) or in which to replace element(s).
x	A list with a number of named elements, referred to as the metadata. See details.

Value

Updated simList object.

Required metadata elements

name	Module name. Must match the filename (without the .R extension). This is currently not parsed by SpaDES.
description	Brief description of the module. This is currently not parsed by SpaDES; it is for human readers only.
keywords	Author-supplied keywords. This is currently not parsed by SpaDES; it is for human readers only.
childModules	If this contains any character vector, then it will be treated as a parent module. If this is a parent module, the
authors	Module author information (as a vector of <code>person()</code> objects. This is currently not parsed by SpaDES; it is
version	Module version number (will be coerced to <code>numeric_version()</code> if a character or numeric are supplied). T
spatialExtent	The spatial extent of the module supplied via <code>terra::ext</code> . This is currently unimplemented. Once implem
timeframe	Vector (length 2) of POSIXt dates specifying the temporal extent of the module. Currently unimplemented.
timeunit	Time scale of the module (e.g., "day", "year"). If this is not specified, then <code>.timeunitDefault()</code> will be us
citation	List of character strings specifying module citation information. Alternatively, a list of filenames of .bib o
documentation	List of filenames referring to module documentation sources. This is currently not parsed by SpaDES; it is
loadOrder	Named list of length 0, 1, or 2, with names being after and before. Each element should be a character st
reqdPkgs	List of R package names required by the module. These packages will be loaded when <code>simInit</code> is called. R
parameters	A data.frame specifying the parameters used in the module. Usually produced by <code>rbind</code> -ing the outputs of
inputObjects	A data.frame specifying the data objects expected as inputs to the module, with columns <code>objectName</code> (cla
outputObjects	A data.frame specifying the data objects output by the module, with columns identical to those in <code>inputO</code>

See Also

`moduleDefaults()`, `defineEvent()`

Examples

```
## a default version of the defineModule is created with a call to newModule
newModule("test", path = tempdir(), open = FALSE)

## view the resulting module file
if (interactive()) file.edit(file.path(tempdir(), "test", "test.R"))
```

defineParameter

Define a parameter used in a module

Description

Used to specify a parameter's name, value, and set a default. The `min` and `max` arguments are ignored by `simInit` or `spades`; they are for human use only. To ensure that a user cannot set parameters outside of a range of values, the module developer should use assertions in their module code.

Usage

```
defineParameter(name, class, default, min, max, desc, ...)
```

Arguments

name	Character string giving the parameter name.
class	Character string giving the parameter class.
default	The default value to use when none is specified by the user. Non-standard evaluation is used for the expression.
min	With max, used to define a suitable range of values. Non-standard evaluation is used for the expression. <i>These are not tested by simInit or spades</i> . These are primarily for human use, i.e., to tell a module user what values the module expects.
max	With min, used to define a suitable range of values. Non-standard evaluation is used for the expression. <i>These are not tested by simInit or spades</i> . These are primarily for human use, i.e., to tell a module user what values the module expects.
desc	Text string providing a brief description of the parameter. If there are extra spaces or carriage returns, these will be stripped, allowing for multi-line character strings without using paste or multiple quotes.
...	A convenience that allows writing a long desc without having to use paste; any character strings after desc will be pasted together with desc.

Value

```
a data.frame
```

Note

Be sure to use the correct NA type: logical (NA), integer (NA_integer_), real (NA_real_), complex (NA_complex_), or character (NA_character_). See [NA\(\)](#).

Examples

```
parameters = rbind(
  defineParameter("lambda", "numeric", 1.23, desc = "intrinsic rate of increase"),
  defineParameter("P", "numeric", 0.2, 0, 1, "probability of attack"),

  # multi-line desc without quotes on each line -- spaces and carriage returns are stripped
  defineParameter("rate", "numeric", 0.2, 0, 1,
```

```

        "rate of arrival. This is in individuals
        per day. This can be modified
        by the user"),
# multi-line desc with quotes on each line
defineParameter("times", "numeric", 0.2, 0, 1,
                desc = "The times during the year ",
                    "that events will occur ",
                    "with possibility of random arrival times")

)

# Create a new module, then access parameters using `P`
tmpdir <- file.path(tmpdir(), "test")
checkPath(tmpdir, create = TRUE)

# creates a new, "empty" module -- it has defaults for everything that is required
newModule("testModule", tmpdir, open = FALSE)

# Look at new module code -- see defineParameter
if (interactive()) file.edit(file.path(tmpdir, "testModule", "testModule.R"))

# initialize the simList
if (requireNamespace("ggplot2", quietly = TRUE)) {
  # Some things not necessary in this example, if not interactive (like plotting)
  opts <- if (interactive()) list() else
    options(spades.plot = NA, spades.useRequire = FALSE,
            spades.moduleCodeChecks = FALSE)
  mySim <- simInit(modules = "testModule",
                  paths = list(modulePath = tmpdir))

  # Access one of the parameters -- because this line is not inside a module
  # function, we must specify the module name. If used within a module,
  # we can omit the module name
  P(mySim, module = "testModule") # gets all params in a module
  P(mySim, ".useCache", "testModule") # just one param
  options(opts)
}
unlink(tmpdir, recursive = TRUE)

```

depsEdgeList

Build edge list for module dependency graph

Description

Build edge list for module dependency graph

Usage

```

depsEdgeList(sim, plot)

## S4 method for signature 'simList,logical'
depsEdgeList(sim, plot)

## S4 method for signature 'simList,missing'
depsEdgeList(sim, plot)

```

Arguments

<code>sim</code>	A <code>simList</code> object.
<code>plot</code>	Logical indicating whether the edgelist (and subsequent graph) will be used for plotting. If TRUE, duplicated rows (i.e., multiple object dependencies between modules) are removed so that only a single arrow is drawn connecting the modules. Default is FALSE.

Value

A data.table whose first two columns give a list of edges and remaining columns the attributes of the dependency objects (object name, class, etc.).

Author(s)

Alex Chubaty

depsGraph	<i>Build a module dependency graph</i>
-----------	--

Description

Build a module dependency graph

Usage

```

depsGraph(sim, plot)

## S4 method for signature 'simList,logical'
depsGraph(sim, plot)

## S4 method for signature 'simList,missing'
depsGraph(sim)

```

Arguments

sim	A simList object.
plot	Logical indicating whether the edgelist (and subsequent graph) will be used for plotting. If TRUE, duplicated rows (i.e., multiple object dependencies between modules) are removed so that only a single arrow is drawn connecting the modules. Default is FALSE.

Value

An igraph() object.

dhour	<i>SpaDES time units</i>
-------	--------------------------

Description

SpaDES modules commonly use approximate durations that divide with no remainder among themselves. For example, models that simulate based on a "week" timestep, will likely want to fall in lock step with a second module that is a "year" timestep. Since, weeks, months, years don't really have this behaviour because of: leap years, leap seconds, not quite 52 weeks in a year, months that are of different duration, etc. We have generated a set of units that work well together that are based on the astronomical or "Julian" year. In an astronomical year, leap years are added within each year with an extra 1/4 day, (i.e., 1 year == 365.25 days); months are defined as year/12, and weeks as year/52.

Usage

```
dhour(x)

dmin(x)

dday(x)

dyears(x)

## S4 method for signature 'numeric'
dyears(x)

dmonths(x)

## S4 method for signature 'numeric'
dmonths(x)
```

```

dweeks(x)

## S4 method for signature 'numeric'
dweeks(x)

dweek(x)

dmonth(x)

dyear(x)

dsecond(x)

dNA(x)

## S4 method for signature 'ANY'
dNA(x)

```

Arguments

`x` numeric. Number of the desired units

Details

When these units are not correct, a module developer can create their own time unit, and create a function to calculate the number of seconds in that unit using the "d" prefix (for duration), following the lubridate package standard: `ddecade <- function(x) lubridate::duration(dyear(10))`. Then the module developer can use "decade" as the module's time unit.

Value

Number of seconds within each unit

Author(s)

Eliot McIntire

downloadData

Download module data

Description

Download external data for a module if not already present in the module directory, or if there is a checksum mismatch indicating that the file is not the correct one.

Usage

```
downloadData(  
  module,  
  path,  
  quiet,  
  quickCheck = FALSE,  
  overwrite = FALSE,  
  files = NULL,  
  checked = NULL,  
  urls = NULL,  
  children = NULL,  
  ...  
)  
  
## S4 method for signature 'character,character,logical'  
downloadData(  
  module,  
  path,  
  quiet,  
  quickCheck = FALSE,  
  overwrite = FALSE,  
  files = NULL,  
  checked = NULL,  
  urls = NULL,  
  children = NULL,  
  ...  
)  
  
## S4 method for signature 'character,missing,missing'  
downloadData(module, quickCheck, overwrite, files, checked, urls, children)  
  
## S4 method for signature 'character,missing,logical'  
downloadData(  
  module,  
  quiet,  
  quickCheck,  
  overwrite,  
  files,  
  checked,  
  urls,  
  children  
)  
  
## S4 method for signature 'character,character,missing'  
downloadData(  
  module,  
  path,  
  quickCheck,
```

```

    overwrite,
    files,
    checked,
    urls,
    children
  )

```

Arguments

<code>module</code>	Character string giving the name of the module.
<code>path</code>	Character string giving the path to the module directory.
<code>quiet</code>	Logical. This is passed to <code>download.file</code> . Default is <code>FALSE</code> .
<code>quickCheck</code>	Logical. If <code>TRUE</code> , then the check with local data will only use <code>file.size</code> instead of <code>digest::digest</code> . This is faster, but potentially much less robust.
<code>overwrite</code>	Logical. Should local data files be overwritten in case they exist? Default is <code>FALSE</code> .
<code>files</code>	A character vector of length 1 or more if only a subset of files should be checked in the 'CHECKSUMS.txt' file.
<code>checked</code>	The result of a previous checksums call. This should only be used when there is no possibility that the file has changed, i.e., if <code>downloadData</code> is called from inside another function.
<code>urls</code>	Character vector of urls from which to get the data. This is automatically found from module metadata when this function invoked with <code>SpaDES.core::downloadModule(..., data = TRUE)</code> . See also prepInputs() .
<code>children</code>	The character vector of child modules (without path) to also run <code>downloadData</code> on
<code>...</code>	Passed to reproducible::preProcess() , e.g., <code>purge</code>

Details

`downloadData` requires a checksums file to work, as it will only download the files specified therein. Hence, module developers should make sure they have manually downloaded all the necessary data and ran checksums to build a checksums file.

There is an experimental attempt to use the **googledrive** package to download data from a shared (publicly or with individual users) file. To try this, put the Google Drive URL in `sourceURL` argument of `expectsInputs` in the module metadata, and put the filename once downloaded in the `objectName` argument. If using RStudio Server, you may need to use "out of band" authentication by setting `options(httr_oob_default = TRUE)`. To avoid caching of Oauth credentials, set `options(httr_oauth_cache = TRUE)`.

There is also an experimental option for the user to make a new 'CHECKSUMS.txt' file if there is a `sourceURL` but no entry for that file. This is experimental and should be used with caution.

Value

Invisibly, a list of downloaded files.

Author(s)

Alex Chubaty & Eliot McIntire

See Also

[prepInputs\(\)](#), [checksums\(\)](#), and [downloadModule\(\)](#) for downloading modules and building a checksums file.

Examples

```
# In metadata, each expectsInput has a sourceURL; downloadData will look for
# that and download if it defined; however this sample module has all
# NAs for sourceURL, so nothing to download
modulePath <- getSampleModules(tempdir())
downloadData("caribouMovement", path = modulePath)
```

downloadModule

Download a module from a SpaDES module GitHub repository

Description

Download a .zip file of the module and extract (unzip) it to a user-specified location.

Usage

```
downloadModule(
  name,
  path,
  version,
  repo,
  data,
  quiet,
  quickCheck = FALSE,
  overwrite = FALSE
)

## S4 method for signature
## 'character,character,character,character,logical,logical,ANY,logical'
downloadModule(
  name,
  path,
  version,
  repo,
  data,
  quiet,
```

```

    quickCheck = FALSE,
    overwrite = FALSE
  )

## S4 method for signature
## 'character,missing,missing,missing,missing,missing,ANY,ANY'
downloadModule(name, quickCheck, overwrite)

## S4 method for signature 'character,ANY,ANY,ANY,ANY,ANY,ANY,ANY,ANY'
downloadModule(
  name,
  path,
  version,
  repo,
  data,
  quiet,
  quickCheck = FALSE,
  overwrite = FALSE
)
```

Arguments

name	Character string giving the module name.
path	Character string giving the location in which to save the downloaded module.
version	The module version to download. (If not specified, or NA, the most recent version will be retrieved.)
repo	GitHub repository name, specified as "username/repo". Default is "PredictiveEcology/SpaDES-modu" which is specified by the global option <code>spades.moduleRepo</code> . Only master/main branches can be used at this point.
data	Logical. If TRUE, then the data that is identified in the module metadata will be downloaded, if possible. Default FALSE.
quiet	Logical. This is passed to <code>download.file</code> (default FALSE).
quickCheck	Logical. If TRUE, then the check with local data will only use <code>file.size</code> instead of <code>digest::digest</code> . This is faster, but potentially much less robust.
overwrite	Logical. Should local module files be overwritten in case they exist? Default FALSE.

Details

Currently only works with GitHub repositories where modules are located in a `modules` directory in the root tree on the master branch. Module `.zip` files' names should contain the version number and be inside their respective module folders (see [zipModule\(\)](#) for zip compression of modules).

Value

A list of length 2. The first element is a character vector containing a character vector of extracted files for the module. The second element is a `tbl` with details about the data that is relevant for the

function, including whether it was downloaded or not, and whether it was renamed (because there was a local copy that had the wrong file name).

Note

downloadModule uses the GITHUB_PAT environment variable if a value is set. This alleviates 403 errors caused by too-frequent downloads. Generate a GitHub personal access token with no additional permissions at <https://github.com/settings/tokens>, and add this key to '.Renviron' as GITHUB_PAT=<your-github-pat-here>.

The default is to overwrite any existing files in the case of a conflict.

Author(s)

Alex Chubaty

See Also

[zipModule\(\)](#) for creating module .zip folders.

envir	<i>Simulation environment</i>
-------	-------------------------------

Description

Accessor functions for the .xData slot, which is the default virtual slot for an S4 class object that inherits from an S3 object (specifically, the simList inherits from environment) in a simList object. These are included for advanced users.

Usage

```
envir(sim)

## S4 method for signature 'simList'
envir(sim)

envir(sim) <- value

## S4 replacement method for signature 'simList'
envir(sim) <- value
```

Arguments

sim	A simList object from which to extract element(s) or in which to replace element(s).
value	The object to be stored at the slot.

Details

Currently, only get and set methods are defined. Subset methods are not.

Value

Returns or sets the value of the slot from the `simList` object.

Author(s)

Alex Chubaty

See Also

[SpaDES.core-package](#), specifically the section 1.2.8 on `simList` environment.

Other functions to access elements of a 'simList' object: [.addDepends\(\)](#), [checkpointFile\(\)](#), [events\(\)](#), [globals\(\)](#), [inputs\(\)](#), [modules\(\)](#), [objs\(\)](#), [packages\(\)](#), [params\(\)](#), [paths\(\)](#), [progressInterval\(\)](#), [times\(\)](#)

eventDiagram	<i>Simulation event diagram</i>
--------------	---------------------------------

Description

Create a Gantt Chart representing the events in a completed simulation. This event diagram is constructed using the completed event list. To change the number of events shown, provide an `n` argument.

Usage

```
eventDiagram(sim, n, startDate, ...)

## S4 method for signature 'simList,numeric,character'
eventDiagram(sim, n, startDate, ...)

## S4 method for signature 'simList,missing,character'
eventDiagram(sim, n, startDate, ...)

## S4 method for signature 'simList,missing,missing'
eventDiagram(sim, n, startDate, ...)
```

Arguments

<code>sim</code>	A <code>simList</code> object (typically corresponding to a completed simulation).
<code>n</code>	The number of most recently completed events to plot.
<code>startDate</code>	A character representation of date in YYYY-MM-DD format.
<code>...</code>	Additional arguments passed to mermaid. Useful for specifying height and width.

Details

Simulation time is presented on the x-axis, starting at date `startDate`. Each module appears in a colour-coded row, within which each event for that module is displayed corresponding to the sequence of events for that module. Note that only the start time of the event is meaningful in these figures: the width of the bar associated with a particular module's event DOES NOT correspond to an event's "duration".

Based on this Stack Overflow answer: <https://stackoverflow.com/a/29999300/1380598>.

Value

Plots an event diagram as Gantt Chart, invisibly returning a mermaid object.

Note

A red vertical line corresponding to the current date may appear on the figure. This is useful for Gantt Charts generally but can be considered a 'bug' here.

Author(s)

Alex Chubaty

See Also

`DiagrammeR::mermaid`.

events

Simulation event lists

Description

Accessor functions for the events and completed slots of a `simList` object. These path functions will extract the values that were provided to the `simInit` function in the `path` argument.

Usage

```
events(sim, unit)

## S4 method for signature 'simList,character'
events(sim, unit)

## S4 method for signature 'simList,missing'
events(sim, unit)

events(sim) <- value

## S4 replacement method for signature 'simList'
events(sim) <- value
```

```

conditionalEvents(sim, unit)

## S4 method for signature 'simList,character'
conditionalEvents(sim, unit)

## S4 method for signature 'simList,missing'
conditionalEvents(sim, unit)

current(sim, unit)

## S4 method for signature 'simList,character'
current(sim, unit)

## S4 method for signature 'simList,missing'
current(sim, unit)

current(sim) <- value

## S4 replacement method for signature 'simList'
current(sim) <- value

completed(sim, unit, times = TRUE)

## S4 method for signature 'simList,character'
completed(sim, unit, times = TRUE)

## S4 method for signature 'simList,missing'
completed(sim, unit, times = TRUE)

completed(sim) <- value

## S4 replacement method for signature 'simList'
completed(sim) <- value

```

Arguments

<code>sim</code>	A <code>simList</code> object from which to extract element(s) or in which to replace element(s).
<code>unit</code>	Character. One of the time units used in SpaDES.
<code>value</code>	The object to be stored at the slot.
<code>times</code>	Logical. Should this function report the <code>clockTime</code> .

Details

By default, the event lists are shown when the `simList` object is printed, thus most users will not require direct use of these methods.

events	Scheduled simulation events (the event queue).
completed	Completed simulation events.

Currently, only get and set methods are defined. Subset methods are not.

Value

Returns or sets the value of the slot from the `simList` object.

Note

Each event is represented by a `data.table()` row consisting of:

- `eventTime`: The time the event is to occur.
- `moduleName`: The module from which the event is taken.
- `eventType`: A character string for the programmer-defined event type.

See Also

[SpaDES.core-package](#), specifically the section 1.2.6 on Simulation event queues.

Other functions to access elements of a 'simList' object: `.addDepends()`, `checkpointFile()`, `envir()`, `globals()`, `inputs()`, `modules()`, `objs()`, `packages()`, `params()`, `paths()`, `progressInterval()`, `times()`

expectsInput	<i>Define an input object that the module expects.</i>
--------------	--

Description

Used to specify an input object's name, class, description, source url and other specifications.

Usage

```
expectsInput(objectName, objectClass, desc, sourceURL, ...)

## S4 method for signature 'ANY,ANY,ANY,ANY'
expectsInput(objectName, objectClass, desc, sourceURL, ...)

## S4 method for signature 'character,character,character,character'
expectsInput(objectName, objectClass, desc, sourceURL, ...)

## S4 method for signature 'character,character,character,missing'
expectsInput(objectName, objectClass, desc, sourceURL, ...)
```

Arguments

objectName	Character string to define the input object's name.
objectClass	Character string to specify the input object's class.
desc	Text string providing a brief description of the input object. If there are extra spaces or carriage returns, these will be stripped, allowing for multi-line character strings without using paste or multiple quotes.
sourceURL	Character string to specify an URL to reach the input object, default is NA.
...	Other specifications of the input object.

Value

A data.frame suitable to be passed to inputObjects in a module's metadata.

Author(s)

Yong Luo

Examples

```
inputObjects <- bindrows(
  expectsInput(objectName = "inputObject1", objectClass = "character",
    desc = "this is for example", sourceURL = "not available"),
  expectsInput(objectName = "inputObject2", objectClass = "numeric",
    desc = "this is for example", sourceURL = "not available",
    otherInformation = "I am the second input object")
)
```

extractURL

Extract a url from module metadata

Description

This will get the sourceURL for the object named.

Usage

```
extractURL(objectName, sim, module)

## S4 method for signature 'character,missing'
extractURL(objectName, sim, module)

## S4 method for signature 'character,simList'
extractURL(objectName, sim, module)
```

Arguments

objectName	A character string of the object name in the metadata.
sim	A simList object from which to extract the sourceURL
module	An optional character string of the module name whose metadata is to be used. If omitted, the function will use the currentModule(sim), if defined.

Value

The url.

Author(s)

Eliot McIntire

fileName	<i>Extract filename (without extension) of a file</i>
----------	---

Description

Extract filename (without extension) of a file

Usage

```
fileName(x)
```

Arguments

x	List or character vector
---	--------------------------

Value

A character vector.

Author(s)

Eliot McIntire

getMapPath	<i>Get copies of sample files for examples and tests</i>
------------	--

Description

Get copies of sample files for examples and tests

Usage

```
getMapPath(tmpdir)

getSampleModules(tmpdir)
```

Arguments

tmpdir	character specifying the path to a temporary directory (e.g., <code>tempdir()</code>)
--------	--

Value

character vector of filepaths to the copied files

getModuleVersion	<i>Find the latest module version from a SpaDES module repository</i>
------------------	---

Description

Modified from <https://stackoverflow.com/a/25485782/1380598>.

Usage

```
getModuleVersion(name, repo)

## S4 method for signature 'character,character'
getModuleVersion(name, repo)

## S4 method for signature 'character,missing'
getModuleVersion(name)
```

Arguments

name	Character string giving the module name.
repo	GitHub repository name, specified as "username/repo". Default is "PredictiveEcology/SpaDES-modu" which is specified by the global option <code>spades.moduleRepo</code> . Only master/main branches can be used at this point.

Details

`getModuleVersion` extracts a module's most recent version by looking at the module `'.zip'` files contained in the module directory. It takes the most recent version, based on the name of the zip file.

See the modules vignette for details of module directory structure (<https://spades-core.predictiveecology.org/articles/ii-modules.html#module-directory-structure-modulename>), and see our SpaDES-modules repo for details of module repository structure (<https://github.com/PredictiveEcology/SpaDES-modules>).

Value

numeric_version

Author(s)

Alex Chubaty

See Also

[zipModule\(\)](#) for creating module `'.zip'` folders.

globals

Get and set global simulation parameters

Description

`globals`, and the alias `G`, accesses or sets the "globals" in the `simList`. This currently is not an explicit slot in the `simList`, but it is a `.globals` element in the `params` slot of the `simList`.

Usage

```
globals(sim)

## S4 method for signature 'simList'
globals(sim)

globals(sim) <- value

## S4 replacement method for signature 'simList'
globals(sim) <- value

G(sim)

## S4 method for signature 'simList'
G(sim)

G(sim) <- value
```

```
## S4 replacement method for signature 'simList'
G(sim) <- value
```

Arguments

sim	A simList object from which to extract element(s) or in which to replace element(s).
value	The parameter value to be set (in the corresponding module and param).

See Also

[SpaDES.core-package](#), specifically the section 1.2.1 on Simulation Parameters.

Other functions to access elements of a 'simList' object: [.addDepends\(\)](#), [checkpointFile\(\)](#), [envir\(\)](#), [events\(\)](#), [inputs\(\)](#), [modules\(\)](#), [objs\(\)](#), [packages\(\)](#), [params\(\)](#), [paths\(\)](#), [progressInterval\(\)](#), [times\(\)](#)

```
initialize,simList-method
```

Generate a simList object

Description

Given the name or the definition of a class, plus optionally data to be included in the object, new returns an object from that class.

Given the name or the definition of a class, plus optionally data to be included in the object, new returns an object from that class.

Usage

```
## S4 method for signature 'simList'
initialize(.Object, ...)

## S4 method for signature 'simList_'
initialize(.Object, ...)
```

Arguments

.Object	A simList object.
...	Optional Values passed to any or all slot

inputObjects	<i>Metadata accessors</i>
--------------	---------------------------

Description

These accessors extract the metadata for a module (if specified) or all modules in a `simList` if not specified.

Usage

```
inputObjects(sim, module, path)

## S4 method for signature 'simList'
inputObjects(sim, module, path)

## S4 method for signature 'missing'
inputObjects(sim, module, path)

outputObjects(sim, module, path)

## S4 method for signature 'simList'
outputObjects(sim, module, path)

## S4 method for signature 'missing'
outputObjects(sim, module, path)

outputObjectNames(sim, module)

## S4 method for signature 'simList'
outputObjectNames(sim, module)

reqdPkgs(sim, module, modulePath)

## S4 method for signature 'simList'
reqdPkgs(sim, module, modulePath)

## S4 method for signature 'missing'
reqdPkgs(sim, module, modulePath)

documentation(sim, module)

## S4 method for signature 'simList'
documentation(sim, module)

sessInfo(sim)

## S4 method for signature 'simList'
```

```
sessInfo(sim)
```

Arguments

sim	A simList object from which to extract element(s) or in which to replace element(s).
module	Character vector of module name(s)
path	The path to the module., i.e., the modulePath. Only relevant if sim not supplied.
modulePath	That path where module can be found. If set already using setPaths, it will use that. This will be ignored if sim is supplied and is required if sim not supplied

Examples

```
# set modulePath
setPaths(modulePath = getSampleModules(tempdir()))
# use Require and reqdPkgs
pkgs <- reqdPkgs(module = c("caribouMovement", "randomLandscapes", "fireSpread"))
```

inputs	<i>Simulation inputs</i>
--------	--------------------------

Description

Accessor functions for the inputs slots in a simList object.

Usage

```
inputs(sim)

## S4 method for signature 'simList'
inputs(sim)

inputs(sim) <- value

## S4 replacement method for signature 'simList'
inputs(sim) <- value

inputArgs(sim)

## S4 method for signature 'simList'
inputArgs(sim)

inputArgs(sim) <- value

## S4 replacement method for signature 'simList'
inputArgs(sim) <- value
```

in the `simInit` call. e.g., the following code would look to see if the user had passed `defaultColor` into during `simInit`. If the user had done this, then this function would not override that value with 'red'. If the user has not passed in a value for `defaultColor`, then the module will get it here:

```
if (!('defaultColor' %in% sim$.userSuppliedObjNames)) { sim$defaultColor <- 'red' }
```

See Also

[SpaDES.core-package](#), specifically the section 1.2.2 on loading and saving.

Other functions to access elements of a 'simList' object: [.addDepends\(\)](#), [checkpointFile\(\)](#), [envir\(\)](#), [events\(\)](#), [globals\(\)](#), [modules\(\)](#), [objs\(\)](#), [packages\(\)](#), [params\(\)](#), [paths\(\)](#), [progressInterval\(\)](#), [times\(\)](#)

Examples

```
#####
# inputs
#####

# Start with a basic empty simList
sim <- simInit()

test <- 1:10
tmpdir <- file.path(tempdir(), "inputs") |> checkPath(create = TRUE)
tmpFile <- file.path(tmpdir, "test.rds")
saveRDS(test, file = tmpFile)
inputs(sim) <- data.frame(file = tmpFile) # using only required column, "file"
inputs(sim) # see that it is not yet loaded, but when it is scheduled to be loaded
simOut <- spades(sim)
inputs(simOut) # confirm it was loaded
simOut$test

# can put data.frame for inputs directly inside simInit call
allTifs <- dir(getMapPath(tempdir()), full.names = TRUE)

# next: .objectNames are taken from the filenames (without the extension)
# This will load all 5 tifs in the SpaDES sample directory, using
# the rast fuction in the terra package, all at time = 0
sim <- simInit(
  inputs = data.frame(
    files = allTifs,
    functions = "rast",
    package = "terra",
    loadTime = 0,
    stringsAsFactors = FALSE)
)

#####
# A fully described inputs object, including arguments:
files <- dir(getMapPath(tempdir()), full.names = TRUE)

# arguments must be a list of lists. This may require I() to keep it as a list
```

```

# once it gets coerced into the data.frame.
# arguments = I(rep(list(native = TRUE), length(files)))
filelist <- data.frame(
  objectName = paste0("Maps", 1:5),
  files = files,
  functions = "terra::rast",
  # arguments = arguments,
  loadTime = 0,
  intervals = c(rep(NA, length(files) - 1), 10)
)
inputs(sim) <- filelist
spades(sim)

# Example showing loading multiple objects from global environment onto the
# same object in the simList, but at different load times
a1 <- 1
a2 <- 2
# Note arguments must be a list of NROW(inputs), with each element itself being a list,
# which is passed to do.call(fun[x], arguments[[x]]), where x is row number, one at a time
args <- lapply(1:2, function(x) {
  list(x = paste0("a", x),
       envir = environment()) # may be necessary to specify in which envir a1, a2
                              # are located, if not in an interactive session
})
inputs <- data.frame(objectName = "a", loadTime = 1:2, fun = "base::get", arguments = I(args))
a <- simInit(inputs = inputs, times = list(start = 0, end = 1))
a <- spades(a)
identical(a1, a$a)

end(a) <- 3
a <- spades(a) # different object (a2) loaded onto a$a
identical(a2, a$a)

# Clean up after
unlink(tmpdir, recursive = TRUE)

```

inSeconds

Convert time units

Description

Current pre-defined units are found within the `spadesTimes()` function. The user can define a new unit. The unit name can be anything, but the function definition must be of the form "dunitName", e.g., `dyear` or `dfortnight`. The unit name is the part without the `d` and the function name definition includes the `d`. This new function, e.g., `dfortnight <- function(x) lubridate::duration(dday(14))` can be placed anywhere in the search path or in a module (you will need to declare "lubridate" in your `pkgDepends` in the metadata).

This function takes a numeric with a "unit" attribute and converts it to another numeric with a different time attribute. If the units passed to argument `units` are the same as `attr("time", "unit")`, then it simply returns input time.

Usage

```

inSeconds(unit, envir, skipChecks = FALSE)

convertTimeunit(time, unit, envir, skipChecks = FALSE)

.spadesTimes

spadesTimes()

checkTimeunit(unit, envir)

## S4 method for signature 'character,missing'
checkTimeunit(unit, envir)

## S4 method for signature 'character,environment'
checkTimeunit(unit, envir)

```

Arguments

<code>unit</code>	Character. One of the time units used in SpaDES or user defined time unit, given as the unit name only. See details.
<code>envir</code>	An environment. This is where to look up the function definition for the time unit. See details.
<code>skipChecks</code>	For speed, the internal checks for classes and missingness can be skipped. Default FALSE.
<code>time</code>	Numeric. With a unit attribute, indicating the time unit of the input numeric. See Details.

Format

An object of class character of length 12.

Details

Because of R scoping, if `envir` is a `simList` environment, then this function will search there first, then up the current `search()` path. Thus, it will find a user defined or module defined unit before a SpaDES unit. This means that a user can override the `dyear` given in SpaDES, for example, which is 365.25 days, with `dyear <- function(x) lubridate::duration(dday(365))`.

If `time` has no unit attribute, then it is assumed to be seconds.

Value

A numeric vector of length 1, with unit attribute set to "seconds".

Author(s)

Alex Chubaty & Eliot McIntire
 Eliot McIntire

loadSimList	<i>Load a saved simList and ancillary files</i>
-------------	---

Description

Loading a `simList` from file can be problematic as there are non-standard objects that must be rebuilt. See description in [saveSimList\(\)](#) for details.

`unzipSimList` is a convenience wrapper around `unzip` and `loadSimList` where all the files are correctly identified and passed to `loadSimList(..., otherFiles = xxx)`. See [zipSimList](#) for details.

Usage

```
loadSimList(
  filename,
  projectPath = getwd(),
  tempPath = tempdir(),
  paths = NULL,
  otherFiles = "",
  verbose = getOption("reproducible.verbose")
)

unzipSimList(zipfile, load = TRUE, paths = getPaths(), ...)
```

Arguments

<code>filename</code>	Character giving the name of a saved simulation file. Currently, only file types <code>.qs</code> or <code>.rds</code> are supported.
<code>projectPath</code>	An optional path for the project within which the <code>simList</code> exists. This is used to identify relative paths for saving and loading the <code>simList</code> .
<code>tempPath</code>	A character string specifying the new base directory for the temporary paths maintained in a <code>simList</code> .
<code>paths</code>	A list of character vectors for all the <code>simList</code> paths. When loading a <code>simList</code> , this will replace the paths of everything to these new paths. Experimental still.
<code>otherFiles</code>	A character vector of (absolute) file names locating each of the existing file-backed Raster* files that are the real paths for the possibly incorrect paths in <code>FileNames(sim)</code> if the file being read in is from a different computer, path, or drive. This could be the output from <code>unzipSimList</code> (which is calls <code>loadSimList</code> internally, passing the unzipped filenames)
<code>verbose</code>	Numeric, -1 silent (where possible), 0 being very quiet, 1 showing more messaging, 2 being more messaging, etc. Default is 1. Above 3 will output much more information about the internals of Caching, which may help diagnose Caching challenges. Can set globally with an option, e.g., <code>options('reproducible.verbose' = 0)</code> to reduce t
<code>zipfile</code>	Filename of a zipped <code>simList</code>
<code>load</code>	Logical. If TRUE, the default, then the <code>simList</code> will also be loaded into R.
<code>...</code>	passed to <code>unzip</code>

Details

If cache is used, it is likely that it should be trimmed before zipping, to include only cache elements that are relevant.

Value

For `loadSimList()`, a `simList` object. For `unzipSimList()`, either a character vector of file names unzipped (if `load = FALSE`), or a `simList` object.

See Also

`saveSimList()`, `zipSimList()`

`makeMemoisable.simList`

Make simList correctly work with memoise

Description

Because of the environment slot, `simList` objects don't correctly memoise a `simList`. This method for `simList` converts the object to a `simList_` first.

Usage

```
## S3 method for class 'simList'
makeMemoisable(x)

## S3 method for class 'simList_'
unmakeMemoisable(x)
```

Arguments

`x` An object to make memoisable. See individual methods in other packages.

Value

A `simList_` object or a `simList`, in the case of `unmakeMemoisable`.

See Also

`reproducible::makeMemoisable()`

maxTimeunit	<i>Determine the largest timestep unit in a simulation</i>
-------------	--

Description

Determine the largest timestep unit in a simulation

Usage

```
maxTimeunit(sim)

## S4 method for signature 'simList'
maxTimeunit(sim)
```

Arguments

sim A simList simulation object.

Value

The timeunit as a character string. This defaults to NA if none of the modules has explicit units.

Author(s)

Eliot McIntire and Alex Chubaty

memoryUseThisSession	<i>Estimate memory used with system("ps")</i>
----------------------	---

Description

This will give a slightly different estimate than `pryr::mem_used`, which uses `gc()` internally. The purpose of this function is to allow continuous monitoring, external to the R session. Normally, this is run in a different session.

This will only work if the user has specified before running the spades call, set the interval, in seconds, that ps is run. E.g., `options("spades.memoryUseInterval" = 0.5)`, will assess memory use every 0.5 seconds. The default is 0, meaning no interval, "off".

Usage

```
memoryUseThisSession(thisPid)

memoryUse(sim, max = TRUE)
```

Arguments

thisPid	Numeric or integer, the PID of the process. If omitted, it will be found with <code>Sys.getpid()</code> .
sim	A completed <code>simList</code>
max	Logical. If TRUE, then the return value will be summarized by module/event, showing the maximum memory used. If FALSE, then the raw memory used during each event will be shown.

Value

estimated memory use in MiB
 data.table summarizing the estimated memory use (in MiB) for each event type, for each module, during the simulation.

Note

The suggested `future` and `future.callr` packages must be available.

See Also

The vignette("iv-modules")

minTimeunit	<i>Determine the smallest timeunit in a simulation</i>
-------------	--

Description

When modules have different timeunit, SpaDES automatically takes the smallest (e.g., "second") as the unit for a simulation.

Usage

```
minTimeunit(sim)

## S4 method for signature 'simList'
minTimeunit(sim)

## S4 method for signature 'list'
minTimeunit(sim)
```

Arguments

sim	A <code>simList</code> simulation object.
-----	---

Value

The timeunit as a character string. This defaults to "second" if none of the modules has explicit units.

Author(s)

Eliot McIntire

moduleCodeFiles	<i>Extract the full file paths for R source code</i>
-----------------	--

Description

This can be used e.g., for Caching, to identify which files have changed.

Usage

```
moduleCodeFiles(paths, modules)
```

Arguments

paths	An optional named list with up to 4 named elements, modulePath, inputPath, outputPath, and cachePath. See details. NOTE: Experimental feature now allows for multiple modulePaths to be specified in a character vector. The modules will be searched for sequentially in the first modulePath, then if it doesn't find it, in the second etc.
modules	A named list of character strings specifying the names of modules to be loaded for the simulation. Note: the module name should correspond to the R source file from which the module is loaded. Example: a module named "caribou" will be sourced from the file 'caribou.R', located at the specified modulePath(simList) (see below).

Value

character vector of file paths.

moduleCoverage	<i>Calculate module coverage of unit tests</i>
----------------	--

Description

Calculate the test coverage by unit tests for the module and its functions.

Usage

```
moduleCoverage(mod, modulePath = "..")
```

Arguments

mod	Character string. The module’s name. Default is <code>basename(getwd())</code>
modulePath	Character string. The path to the module directory (default is <code>".."</code> , i.e., one level up from working directory).

Value

Return a list of two coverage objects and two `data.table` objects. The two coverage objects are named `moduleCoverage` and `functionCoverage`. The `moduleCoverage` object contains the percent value of unit test coverage for the module. The `functionCoverage` object contains percentage values for unit test coverage for each function defined in the module. Please use `covr::report()` to view the coverage information. Two `data.tables` give the information of all the tested and untested functions in the module.

Note

When running this function, the test files must be strictly placed in the ‘tests/testthat/’ directory under module path. To automatically generate this folder, please set `unitTests = TRUE` when creating a new module using `newModule()`. To accurately test your module, the test filename must follow the format `test-functionName.R`.

Author(s)

Yong Luo

See Also

`newModule()`.

moduleDefaults	<i>Defaults values used in defineModule</i>
----------------	---

Description

Where individual elements are missing in `defineModule`, these defaults will be used.

Usage

`moduleDefaults`

Format

An object of class `list` of length 13.

Value

named list of default module metadata

moduleDiagram	<i>Simulation module dependency diagram</i>
---------------	---

Description

Create a network diagram illustrating the simplified module dependencies of a simulation. Offers a less detailed view of specific objects than does plotting the `depsEdgeList` directly with `objectDiagram()`.

Usage

```
moduleDiagram(sim, type, showParents = TRUE, ...)  
  
## S4 method for signature 'simList,character,logical'  
moduleDiagram(sim, type = "plot", showParents = TRUE, ...)  
  
## S4 method for signature 'simList,ANY,ANY'  
moduleDiagram(sim, type, showParents = TRUE, ...)
```

Arguments

<code>sim</code>	A <code>simList</code> object (typically corresponding to a completed simulation).
<code>type</code>	Character string, either <code>"rgl"</code> for <code>igraph::rglplot</code> or <code>"tk"</code> for <code>igraph::tkplot</code> , <code>"Plot"</code> to use <code>quickPlot::Plot()</code> or <code>"plot"</code> to use <code>base::plot()</code> , the default.
<code>showParents</code>	Logical. If <code>TRUE</code> , then any children that are grouped into parent modules will be grouped together by coloured blobs. Internally, this is calling <code>moduleGraph()</code> . Default <code>FALSE</code> .
<code>...</code>	Additional arguments passed to plotting function specified by <code>type</code> .

Value

invoked for its side effect of plotting the module dependency diagram.

Author(s)

Alex Chubaty

See Also

`igraph()`, `moduleGraph()` for a version that accounts for parent and children module structure.

Examples

```

if (requireNamespace("SpaDES.tools", quietly = TRUE) &&
    requireNamespace("NLMR", quietly = TRUE)) {
  library(igraph)
  times <- list(start = 0, end = 6, "month")
  parameters <- list(
    .globals = list(stackName = "landscape"),
    caribouMovement = list(
      .saveObjects = "caribou",
      .saveInitialTime = 1, .saveInterval = 1
    ),
    randomLandscapes = list(.plotInitialTime = NA, nx = 20, ny = 20))

  modules <- list("randomLandscapes", "caribouMovement")
  paths <- list(
    modulePath = getSampleModules(tempdir())
  )

  # Set some options so example runs faster
  opts <- options(spades.moduleCodeChecks = FALSE, spades.loadReqdPkgs = FALSE)
  sim <- simInit(times = times, params = parameters, modules = modules,
    paths = paths)
  options(opts)
  moduleDiagram(sim)
  # Can also use default base::plot
  modDia <- depsGraph(sim, plot = TRUE)
  # See ?plot.igraph
  plot(modDia, layout = layout_as_star)

  # Or for more control - here, change the label "_INPUT_" to "DATA"
  edgeList <- depsEdgeList(sim)
  edgeList <- edgeList[, list(from, to)]
  edgeList[from == "_INPUT_", from := "Data"]
  edgeList[to == "_INPUT_", to := "Data"]
  edgeList <- unique(edgeList)
  ig <- graph_from_data_frame(edgeList[, list(from, to)])
  plot(ig)
}

```

Description

This is still experimental, but this will show the hierarchical structure of parent and children modules and return a list with an igraph object and an igraph communities object, showing the groups. Currently only tested with relatively simple structures.

Usage

```

moduleGraph(sim, plot, ...)

## S4 method for signature 'simList,logical'
moduleGraph(sim, plot, ...)

## S4 method for signature 'simList,missing'
moduleGraph(sim, plot, ...)

```

Arguments

<code>sim</code>	A <code>simList</code> object.
<code>plot</code>	Logical indicating whether the edgelist (and subsequent graph) will be used for plotting. If TRUE, duplicated rows (i.e., multiple object dependencies between modules) are removed so that only a single arrow is drawn connecting the modules. Default is FALSE.
<code>...</code>	Arguments passed to Plot

Value

A list with 2 elements, an `igraph()` object and an `igraph communities` object.

`moduleDiagram()`

moduleMetadata	<i>Parse and extract module metadata</i>
----------------	--

Description

Parse and extract module metadata

Usage

```

moduleMetadata(
  sim,
  module,
  path = getOption("spades.modulePath", NULL),
  defineModuleListItems = c("name", "description", "keywords", "childModules", "authors",
    "version", "spatialExtent", "timeframe", "timeunit", "citation", "documentation",
    "reqdPkgs", "parameters", "inputObjects", "outputObjects")
)

```

```
## S4 method for signature 'missing,character,character'
moduleMetadata(module, path, defineModuleListItems)

## S4 method for signature 'missing,character,missing'
moduleMetadata(module, defineModuleListItems)

## S4 method for signature 'ANY,ANY,ANY'
moduleMetadata(
  sim,
  module,
  path = getOption("spades.modulePath", NULL),
  defineModuleListItems = c("name", "description", "keywords", "childModules", "authors",
    "version", "spatialExtent", "timeframe", "timeunit", "citation", "documentation",
    "reqdPkgs", "parameters", "inputObjects", "outputObjects")
)
```

Arguments

<code>sim</code>	A <code>simList</code> simulation object, generally produced by <code>simInit</code> .
<code>module</code>	Character string. Your module's name.
<code>path</code>	Character string specifying the file path to modules directory. Default is to use the <code>spades.modulePath</code> option.
<code>defineModuleListItems</code>	A vector of metadata entries to return values about.

Value

A list of module metadata, matching the structure in `defineModule()`.

Author(s)

Alex Chubaty

See Also

[defineModule\(\)](#)

Examples

```
## turn off code checking -- don't need it here
opts <- options("spades.moduleCodeChecks" = FALSE,
  "spades.useRequire" = FALSE)

path <- getSampleModules(tempdir())
sampleModules <- dir(path)
x <- moduleMetadata(sampleModules[3], path = path)

## using simList
if (require("SpaDES.tools", quietly = TRUE)) {
```

```

mySim <- simInit(
  times = list(start = 2000.0, end = 2001.0, timeunit = "year"),
  params = list(
    .globals = list(stackName = "landscape")
  ),
  modules = list("caribouMovement"),
  paths = list(modulePath = path)
)
moduleMetadata(sim = mySim)
}

# turn code checking back on -- don't need it here
options(opts)

```

moduleParams

Extract a module's parameters, inputs, or outputs

Description

These are more or less wrappers around moduleMetadata, with the exception that extraneous spaces and End-Of-Line characters will be removed from the desc arguments in defineParameters, defineInputs, and defineOutputs

Usage

```

moduleParams(module, path)

## S4 method for signature 'character,character'
moduleParams(module, path)

moduleInputs(module, path)

## S4 method for signature 'character,character'
moduleInputs(module, path)

moduleOutputs(module, path)

## S4 method for signature 'character,character'
moduleOutputs(module, path)

```

Arguments

module	Character string. Your module's name.
path	Character string specifying the file path to modules directory. Default is to use the spades.modulePath option.

Value

data.frame

i <- moduleInputs(sampleModules[3], path = path)
o <- moduleOutputs(sampleModules[3], path = path)

knitr::kable(p)
knitr::kable(i)
knitr::kable(o)
```

modules

Simulation modules and dependencies

Description

Accessor functions for the depends and modules slots in a `simList` object. These are included for advanced users.

depends()	List of simulation module dependencies. (advanced)
modules()	List of simulation modules to be loaded. (advanced)
inputs()	List of loaded objects used in simulation. (advanced)

Usage

```
modules(sim, hidden = FALSE)

## S4 method for signature 'simList'
modules(sim, hidden = FALSE)

modules(sim) <- value

## S4 replacement method for signature 'simList'
modules(sim) <- value

depends(sim)
```

```
## S4 method for signature 'simList'
depends(sim)

depends(sim) <- value

## S4 replacement method for signature 'simList'
depends(sim) <- value
```

Arguments

sim	A simList object from which to extract element(s) or in which to replace element(s).
hidden	Logical. If TRUE, show the default core modules.
value	The object to be stored at the slot.

Details

Currently, only get and set methods are defined. Subset methods are not.

Value

Returns or sets the value of the slot from the simList object.

Author(s)

Alex Chubaty

moduleVersion

Parse and extract a module's version

Description

Parse and extract a module's version

Usage

```

moduleVersion(module, path, sim, envir = NULL)

## S4 method for signature 'character,character,missing'
moduleVersion(module, path, envir)

## S4 method for signature 'character,missing,missing'
moduleVersion(module, envir)

## S4 method for signature 'character,missing,simList'
moduleVersion(module, sim, envir)

```

Arguments

module	Character string. Your module's name.
path	Character string specifying the file path to modules directory. Default is to use the <code>spades.modulePath</code> option.
sim	A <code>simList</code> simulation object, generally produced by <code>simInit</code> .
envir	Optional environment in which to store parsed code. This may be useful if the same file is being parsed multiple times. This function will check in that environment for the parsed file before parsing again. If the <code>envir</code> is transient, then this will have no effect.

Value

numeric_version indicating the module's version.

Author(s)

Alex Chubaty

[moduleMetadata\(\)](#)

Examples

```

# using filepath
path <- getSampleModules(tempdir())
moduleVersion("caribouMovement", path)

# using simList
options("spades.useRequire" = FALSE)
if (require("SpaDES.tools", quietly = TRUE)) {
  mySim <- simInit(
    times = list(start = 2000.0, end = 2002.0, timeunit = "year"),
    params = list(
      .globals = list(stackName = "landscape", burnStats = "nPixelsBurned")
    ),

```

```

    modules = list("caribouMovement"),
    paths = list(modulePath = path)
  )
  moduleVersion("caribouMovement", sim = mySim)
}

```

newModule

Create new module from template

Description

Generate a skeleton for a new SpaDES module, a template for a documentation file, a citation file, a license file, a 'README.md' file, and a folder that contains unit tests information. The newModuleDocumentation will not generate the module file, but will create the other files.

Usage

```

newModule(name, path, ..., events, envir = parent.frame())

## S4 method for signature 'character,character'
newModule(name, path, ..., events, envir = parent.frame())

## S4 method for signature 'character,missing'
newModule(name, path, ..., events, envir = parent.frame())

```

Arguments

name	Character string specifying the name of the new module.
path	Character string. Subdirectory in which to place the new module code file. The default is the current working directory.
...	Additional arguments. Currently, these can be either named function definitions (which will be added to the simList) or one or more of the following:
	<p>children Required when type = "parent". A character vector specifying the names of child modules.</p> <p>open Logical. Should the new module file be opened after creation? Default TRUE.</p> <p>type Character string specifying one of "child" (default), or "parent".</p> <p>unitTests Logical. Should the new module include unit test files? Default TRUE. Unit testing relies on the testthat package.</p> <p>useGitHub Logical. Is module development happening on GitHub? Default TRUE.</p>
events	A list of named expressions, each of which is surrounded by { }. A user can specify events here, instead of accepting the default doEvent function that comes with the module template. See example.
envir	An environment where objects being passed to newModule can be found. Default parent.frame(), which should be fine for most cases.

Details

All files will be created within a subdirectory named `name` within the path:

```
<path>/
|_ <name>/
|_ R/                # contains additional module R scripts
|_ data/             # directory for all included data
|_ CHECKSUMS.txt     # contains checksums for data files
|_ tests/            # contains unit tests for module code
|_ citation.bib       # bibtex citation for the module
|_ LICENSE            # describes module's legal usage
|_ README.md         # provide overview of key aspects
|_ <name>.R           # module code file (incl. metadata)
|_ <name>.Rmd         # documentation, usage info, etc.
```

Value

NULL (invisibly). The new module file is created at `'path/name.R'`, as well as ancillary files for documentation, citation, `'LICENSE'`, `'README'`, and `'tests'` directory.

Note

On Windows there is currently a bug in RStudio that prevents the editor from opening when `file.edit` is called. Similarly, in RStudio on macOS, there is an issue opening files where they are opened in an overlaid window rather than a new tab. `file.edit` does work if the user types it at the command prompt. A message with the correct lines to copy and paste is provided.

Examples

```
tmpdir <- tempdir2("exampleNewModule")
## create a "myModule" module in the "modules" subdirectory.
newModule("myModule", tmpdir)

## create a new parent module in the "modules" subdirectory.
newModule("myParentModule", tmpdir, type = "parent", children = c("child1", "child2"))
unlink(tmpdir, recursive = TRUE)
```

newModuleCode	<i>Create new module code file</i>
---------------	------------------------------------

Description

Create new module code file

Usage

```
newModuleCode(name, path, ..., events)
```

```
## S4 method for signature 'character,character'
newModuleCode(name, path, ..., events)
```

Arguments

name	Character string specifying the name of the new module.
path	Character string. Subdirectory in which to place the new module code file. The default is the current working directory.
...	Additional arguments. Currently, these can be either named function definitions (which will be added to the simList) or one or more of the following:
	children Required when type = "parent". A character vector specifying the names of child modules.
	open Logical. Should the new module file be opened after creation? Default TRUE.
	type Character string specifying one of "child" (default), or "parent".
events	A list of named expressions, each of which is surrounded by { }. A user can specify events here, instead of accepting the default doEvent function that comes with the module template. See example for newModule() .

Value

NULL (invisibly). Invoked for its side effect of creating new module code files.

`newModuleDocumentation`*Create new module documentation*

Description

Create new module documentation

Usage

```
newModuleDocumentation(name, path, ...)
```

```
## S4 method for signature 'character,character'  
newModuleDocumentation(name, path, ...)
```

```
## S4 method for signature 'character,missing'  
newModuleDocumentation(name, path, ...)
```

Arguments

<code>name</code>	Character string specifying the name of the new module.
<code>path</code>	Character string. Subdirectory in which to place the new module code file. The default is the current working directory.
<code>...</code>	Additional arguments. Currently, these can be either named function definitions (which will be added to the <code>simList</code>) or one or more of the following: <code>children</code> Required when <code>type = "parent"</code> . A character vector specifying the names of child modules. <code>open</code> Logical. Should the new module file be opened after creation? Default <code>TRUE</code> . <code>type</code> Character string specifying one of "child" (default), or "parent".

Value

`NULL` (invisibly). Invoked for its side effect of creating new module code files.

Eliot McIntire and Alex Chubaty

See Also

Other module creation helpers: [newModule\(\)](#), [newModuleCode\(\)](#), [newModuleTests\(\)](#)

newModuleTests	Create template testing structures for new modules
----------------	--

Description

Create template testing structures for new modules

Usage

```
newModuleTests(name, path, open, useGitHub)
```

```
## S4 method for signature 'character,character,logical,logical'  
newModuleTests(name, path, open, useGitHub)
```

Arguments

name	Character string specifying the name of the new module.
path	Character string. Subdirectory in which to place the new module code file. The default is the current working directory.
open	Logical. Should the new module file be opened after creation? Default TRUE in an interactive session.
useGitHub	Logical indicating whether GitHub will be used. If TRUE (default), creates suitable configuration files (e.g., '.gitignore') and configures basic GitHub actions for module code checking.

Value

NULL (invisibly). Invoked for its side effect of creating new module test files.

Author(s)

Eliot McIntire and Alex Chubaty

See Also

Other module creation helpers: [newModule\(\)](#), [newModuleCode\(\)](#), [newModuleDocumentation\(\)](#)

newObjectsCreated	<i>Show which objects were first created in a simInit or spades call</i>
-------------------	--

Description

This does an `rbindlist(sim$._objectsCreated)`. This object in the `sim` records the yellow message that reports on when objects are created.

Usage

```
newObjectsCreated(sim)
```

Arguments

<code>sim</code>	A <code>simList</code> object that contains <code>data.table</code> objects
------------------	---

Value

The `data.table` of the objects created, alongside the `current(sim)` at each moment of creation.

newProgressBar	<i>Progress bar</i>
----------------	---------------------

Description

Shows a progress bar that is scaled to simulation end time.

Usage

```
newProgressBar(sim)
```

```
setProgressBar(sim)
```

Arguments

<code>sim</code>	A <code>simList</code> simulation object.
------------------	---

Details

The progress bar object is stored in a separate environment, `#' .pkgEnv`.

Value

invoked for side effect of creating progress bar

Author(s)

Alex Chubaty and Eliot McIntire

newProject	Create new SpaDES project
------------	---------------------------

Description

Initialize a project with subdirectories 'cache/', 'modules/', 'inputs/', 'outputs/', and setPaths accordingly. If invoked from Rstudio, will also create a new Rstudio project file.

Usage

```
newProject(name, path, open)

## S4 method for signature 'character,character,logical'
newProject(name, path, open)

## S4 method for signature 'character,character,missing'
newProject(name, path, open)
```

Arguments

name	project name (name of project directory)
path	path to directory in which to create the project directory
open	Logical. Should the new project file be opened after creation? Default TRUE in an interactive session.

Value

invoked for side effect of project file creation

Examples

```
myProjDir <- newProject("myProject", tempdir())

dir.exists(file.path(myProjDir, "cache"))
dir.exists(file.path(myProjDir, "inputs"))
dir.exists(file.path(myProjDir, "modules"))
dir.exists(file.path(myProjDir, "outputs"))
unlink(myProjDir, recursive = TRUE) ## cleanup
```

newProjectCode	<i>Create new module code file</i>
----------------	------------------------------------

Description

Create new module code file

Usage

```
newProjectCode(name, path, open)
```

```
## S4 method for signature 'character,character,logical'
newProjectCode(name, path, open = interactive())
```

Arguments

name	project name (name of project directory)
path	path to directory in which to create the project directory
open	Logical. Should the new project file be opened after creation? Default TRUE in an interactive session.

Value

invoked for side effect of project file creation

Author(s)

Alex Chubaty

noEventWarning	<i>Text for no event with that name</i>
----------------	---

Description

Provides the text to be sent to warning in each module as the default switch case.

Usage

```
noEventWarning(sim)
```

Arguments

sim	A simList simulation object, generally produced by simInit.
-----	---

Value

A text string specifying the event name and module for which there is no event

objectDiagram	<i>Simulation object dependency diagram</i>
---------------	---

Description

Create a sequence diagram illustrating the data object dependencies of a simulation. Offers a more detailed view of specific objects than does plotting the `depsEdgeList` directly with `moduleDiagram()`.

Usage

```
objectDiagram(sim, ...)

## S4 method for signature 'simList'
objectDiagram(sim, ...)
```

Arguments

<code>sim</code>	A <code>simList</code> object (typically corresponding to a completed simulation).
<code>...</code>	Additional arguments passed to <code>DiagrammeR::mermaid</code> . Useful for specifying height and width.

Value

Plots a sequence diagram, invisibly returning a `DiagrammeR::mermaid` object.

Author(s)

Alex Chubaty

See Also

`DiagrammeR::mermaid`.

Examples

```
if (requireNamespace("DiagrammeR", quietly = TRUE)) {
  sim <- simInit()
  objectDiagram(sim)
  # if there are lots of objects, may need to increase width and/or height
  objectDiagram(sim, height = 3000, width = 3000)
}
```

objectSynonyms	<i>Identify synonyms in a simList</i>
----------------	---------------------------------------

Description

This will create active bindings amongst the synonyms. To minimize copying, the first one that exists in the character vector will become the "canonical" object. All others named in the character vector will be activeBindings to that canonical one. This synonym list will be assigned to the `envir`, as an object named `objectSynonyms`. That object will have an attribute called, `bindings` indicating which one is the canonical one and which is/are the activeBindings. **EXPERIMENTAL:** If the objects are removed during a `spades` call by, say, a module, then at the end of the event, the `spades` call will replace the bindings. In other words, if a module deletes the object, it will "come back". This may not always be desired.

Usage

```
objectSynonyms(envir, synonyms)
```

Arguments

<code>envir</code>	An environment, which in the context of <code>SpaDES.core</code> is usually a <code>simList</code> to find and/or place the <code>objectSynonyms</code> object.
<code>synonyms</code>	A list of synonym character vectors, such as <code>list(c("age", "ageMap", "age2"), c("veg", "vegMap"))</code>

Details

This is very experimental and only has minimal tests. Please report if this is not working, and under what circumstances (e.g., please submit a reproducible example to our issues tracker)

This function will append any new `objectSynonym` to any pre-existing `objectSynonym` in the `envir`. Similarly, this function assumes transitivity, i.e., if `age` and `ageMap` are synonyms, and `ageMap` and `timeSinceFire` are synonyms, then `age` and `timeSinceFire` must be synonyms.

Value

Active bindings in the `envir` so that all synonyms point to the same canonical object, e.g., they would be at `envir[[synonym[[1]][1]]]` and `envir[[synonym[[1]][2]]]`, if a list of length one is passed into `synonyms`, with a character vector of length two. See examples.

Examples

```
sim <- simInit()

sim$age <- 1:10;
sim <- objectSynonyms(sim, list(c("age", "ageMap")))

identical(sim$ageMap, sim$age)
```

```

sim$age <- 4
identical(sim$ageMap, sim$age)
sim$ageMap <- 2:5
sim$ageMap[3] <- 11
identical(sim$ageMap, sim$age)

# Also works to pass it in as an object
objectSynonyms <- list(c("age", "ageMap"))
sim <- simInit(objects = list(objectSynonyms = objectSynonyms))
identical(sim$ageMap, sim$age) # they are NULL at this point
sim$age <- 1:10
identical(sim$ageMap, sim$age) # they are not NULL at this point

## More complicated, with 'updating' i.e., you can add new synonyms to previous
sim <- simInit()
os <- list(c("age", "ageMap"), c("vegMap", "veg"), c("studyArea", "studyArea2"))
os2 <- list(c("ageMap", "timeSinceFire", "tsf"),
            c("systime", "systime2"),
            c("vegMap", "veg"))
sim <- objectSynonyms(sim, os)
sim <- objectSynonyms(sim, os2)

# check
sim$objectSynonyms

```

 objs

Extract or replace an object from the simulation environment

Description

The `[[` and `$` operators provide "shortcuts" for accessing objects in the simulation environment. I.e., instead of using `envir(sim)$object` or `envir(sim)[["object"]]`, one can simply use `sim$object` or `sim[["object"]]`.

Usage

```

objs(sim, ...)

## S4 method for signature 'simList'
objs(sim, ...)

objs(sim) <- value

## S4 replacement method for signature 'simList'
objs(sim) <- value

moduleObjects(sim, module, path)

```

```
findObjects(objects, sim, module, path)
```

Arguments

<code>sim</code>	A <code>simList</code> object from which to extract element(s) or in which to replace element(s).
<code>...</code>	passed to <code>ls</code>
<code>value</code>	objects to assign to the <code>simList</code>
<code>module</code>	Character vector of module name(s)
<code>path</code>	The path to the module., i.e., the <code>modulePath</code> . Only relevant if <code>sim</code> not supplied.
<code>objects</code>	A character vector of length ≥ 1 with name(s) of objects to look for in the metadata. This is used in a <code>grep</code> , meaning it will do partial matching (e.g., "studyArea" will find "studyArea" and "studyAreaLarge"). User can use regular expressions.

Details

`objs` can take `...` arguments passed to `ls`, allowing, e.g. `all.names=TRUE` `objs<-` requires takes a named list of values to be assigned in the simulation environment.

Value

Returns or sets a list of objects in the `simList` environment.

`moduleObjects` returns a `data.table` with 4 columns, `module`, `objectName`, `type`, and `desc`, pulled directly from the object metadata in the `createsOutputs` and `expectsInputs`. These will be determined either from a `simList` or from the module source code.

`findObjects` returns a `data.table` similar to `moduleObjects`, but with only the objects provided by `objects`.

See Also

[SpaDES.core-package](#), specifically the section 1.2.1 on Simulation Parameters.

Other functions to access elements of a 'simList' object: [.addDepends\(\)](#), [checkpointFile\(\)](#), [envir\(\)](#), [events\(\)](#), [globals\(\)](#), [inputs\(\)](#), [modules\(\)](#), [packages\(\)](#), [params\(\)](#), [paths\(\)](#), [progressInterval\(\)](#), [times\(\)](#)

Examples

```
# findObjects
path <- getSampleModules(tempdir())
findObjects(path = path, module = dir(path), objects = "caribou")
```

objSize.simList	<i>Object size for simList</i>
-----------------	--------------------------------

Description

Recursively, runs `reproducible::objSize()` on the `simList` environment, so it estimates the correct size of functions stored there (e.g., with their enclosing environments) plus, it adds all other "normal" elements of the `simList`, e.g., `objSize(completed(sim))`. The output is structured into 2 elements: the `sim` environment and all its objects, and the other slots in the `simList` (e.g., events, completed, modules, etc.). The returned object also has an attribute, "total", which shows the total size.

Usage

```
## S3 method for class 'simList'
objSize(x, quick = TRUE, ...)
```

Arguments

<code>x</code>	An object
<code>quick</code>	Logical. If FALSE, then an attribute, "objSize" will be added to the returned value, with each of the elements' object size returned also.
<code>...</code>	Additional arguments (currently unused), enables backwards compatible use.

Value

an estimate of the size of the object, in bytes.

Examples

```
a <- simInit(objects = list(d = 1:10, b = 2:20))
objSize(a)
utils::object.size(a)
```

openModules	<i>Open all modules nested within a base directory</i>
-------------	--

Description

This is just a convenience wrapper for opening several modules at once, recursively. A module is defined as any file that ends in `.R` or `.r` and has a directory name identical to its filename. Thus, this must be case sensitive.

Usage

```
openModules(name, path)

## S4 method for signature 'character,character'
openModules(name, path)

## S4 method for signature 'missing,missing'
openModules()

## S4 method for signature 'missing,character'
openModules(path)

## S4 method for signature 'character,missing'
openModules(name)

## S4 method for signature 'simList,missing'
openModules(name)
```

Arguments

name	Character vector with names of modules to open. If missing, then all modules will be opened within the base directory.
path	Character string of length 1. The base directory within which there are only module subdirectories.

Value

NULL (invisibly). All file are open via `file.edit`.

Note

On Windows there is currently a bug in RStudio that prevents the editor from opening when `file.edit` is called. `file.edit` does work if the user types it at the command prompt. A message with the correct lines to copy and paste is provided.

Author(s)

Eliot McIntire

Examples

```
if (interactive())
  openModules("modules")
```

 outputs

Simulation outputs

Description

Accessor functions for the outputs slots in a `simList` object.

If a module saves a file to disk during events, it can be useful to keep track of the files that are saved e.g., for `saveSimList()` so that all files can be added to the archive. In addition to setting outputs at the `simInit` stage, a module developer can also put this in a using any saving mechanism that is relevant (e.g., `qs::qsave`, `saveRDS` etc.). When a module event does this it can be useful to register that saved file. `registerOutputs` offers an additional mechanism to do this. See examples.

Usage

```
outputs(sim)

## S4 method for signature 'simList'
outputs(sim)

outputs(sim) <- value

## S4 replacement method for signature 'simList'
outputs(sim) <- value

registerOutputs(filename, sim, ...)

outputArgs(sim)

## S4 method for signature 'simList'
outputArgs(sim)

outputArgs(sim) <- value

## S4 replacement method for signature 'simList'
outputArgs(sim) <- value
```

Arguments

<code>sim</code>	A <code>simList</code> . If missing, then the function will search in the call stack, so it will find it if it is in a <code>SpaDES</code> module.
<code>value</code>	The object to be stored at the slot. See Details.
<code>filename</code>	The filename to register in the <code>outputs(sim)</code> <code>data.frame</code> . If missing, an attempt will be made to search for either a file or filename argument in the call itself. This means that this function can be used with the pipe, as long as the returned return from the upstream pipe function is a filename or if it is <code>NULL</code> (e.g., <code>saveRDS</code>), then it will find the file argument and use that.
<code>...</code>	Not used.

Details

These functions are one of three mechanisms to add information about which output files to save.

1. As arguments to a `simInit` call. Specifically, `inputs` or `outputs`. See `?simInit`.
2. With the `outputs(simList)` function call.
3. By adding a function called `.inputObjects` inside a module, which will be executed during the `simInit` call. This last way is the most "modular" way to create default data sets for your model.

See below for more details.

Note using `registerOutputs`: a user can pass any other arguments to `registerOutputs` that are in the `outputs(sim)` data.frame, such as `objectName`, `fun`, `package`, though these will not be used to save the files as this function is only about registering an output that has already been saved.

Value

A `simList` which will be the `sim` passed in with a new object registered in the `outputs(sim)`

outputs function or argument in simInit

`outputs` accepts a data.frame similar to the `inputs` data.frame, but with up to 6 columns.

<code>objectName</code>	required, character string indicating the name of the object in the <code>simList</code> that will be saved to disk (without the file)
<code>file</code>	optional, a character string indicating the file path to save to. The default is to concatenate <code>objectName</code> with the
<code>fun</code>	optional, a character string indicating the function to use to save that file. The default is <code>saveRDS()</code>
<code>package</code>	optional character string indicating the package in which to find the fun);
<code>saveTime</code>	optional numeric, indicating when in simulation time the file should be saved. The default is the lowest priority
<code>arguments</code>	is a list of lists of named arguments, one list for each fun. For example, if <code>fun = "write.csv"</code> , <code>arguments = list()</code>

See the modules vignette for more details (`browseVignettes("SpaDES.core")`).

Note

The automatic file type handling only adds the correct extension from a given fun and package. It does not do the inverse, from a given extension find the correct fun and package.

See Also

`registerOutputs()` which enables files that are saved to be added to the `simList` using the `outputs(sim)` mechanism, so the files that are saved during a module event can be tracked at the `simList` level. `saveSimList()` which will optionally add all the outputs that are tracked into an archive.

`Plots()`, `outputs()`

Examples

```
#####
# outputs
#####

tmpdir <- file.path(tmpdir(), "outputs") |> checkPath(create = TRUE)
tmpFile <- file.path(tmpdir, "temp.rds")
tempObj <- 1:10

# Can add data.frame of outputs directly into simInit call
sim <- simInit(objects = c("tempObj"),
               outputs = data.frame(objectName = "tempObj"),
               paths = list(outputPath = tmpdir))
outputs(sim) # To see what will be saved, when, what filename
sim <- spades(sim)
outputs(sim) # To see that it was saved, when, what filename

# Also can add using assignment after a simList object has been made
sim <- simInit(objects = c("tempObj"), paths = list(outputPath = tmpdir))
outputs(sim) <- data.frame(objectName = "tempObj", saveTime = 1:10)
sim <- spades(sim)
outputs(sim) # To see that it was saved, when, what filename.

# can do highly variable saving
tempObj2 <- paste("val", 1:10)
df1 <- data.frame(col1 = tempObj, col2 = tempObj2)
sim <- simInit(objects = c("tempObj", "tempObj2", "df1"),
               paths = list(outputPath = tmpdir))
outputs(sim) <- data.frame(
  objectName = c(rep("tempObj", 2), rep("tempObj2", 3), "df1"),
  saveTime = c(c(1, 4), c(2, 6, 7), end(sim)),
  fun = c(rep("saveRDS", 5), "write.csv"),
  package = c(rep("base", 5), "utils"),
  stringsAsFactors = FALSE)
# since write.csv has a default of adding a column, x, with rownames, must add additional
# argument for 6th row in data.frame (corresponding to the write.csv function)
outputArgs(sim)[[6]] <- list(row.names = FALSE)
sim <- spades(sim)
outputs(sim)

# read one back in just to test it all worked as planned
newObj <- read.csv(dir(tmpdir, pattern = "year10.csv", full.name = TRUE))
newObj

# using saving with SpaDES-aware methods
# To see current ones SpaDES can do
.saveFileExtensions()

library(terra)
ras <- rast(ncol = 4, nrow = 5)
ras[] <- 1:20
```

```

sim <- simInit(objects = c("ras"), paths = list(outputPath = tmpdir))
outputs(sim) <- data.frame(
  file = "test",
  fun = "writeRaster",
  package = "terra",
  objectName = "ras",
  stringsAsFactors = FALSE)

simOut <- spades(sim)
outputs(simOut)
newRas <- rast(dir(tmpdir, full.name = TRUE, pattern = ".tif")[1])
all.equal(newRas, ras) # Should be TRUE
# Clean up after
unlink(tmpdir, recursive = TRUE)
# For `registerOutputs`
sim <- simInit()
# This would normally be a save call, e.g., `writeRaster`
tf <- reproducible::tempfile2(fileext = ".tif")
sim <- registerOutputs(sim, filename = tf)

# Using a pipe
tf <- reproducible::tempfile2(fileext = ".rds")
sim$a <- 1
sim <- saveRDS(sim$a, tf) |> registerOutputs()
# confirm:
outputs(sim) # has object --> saved = TRUE

```

packages

Get module or simulation package dependencies

Description

Get module or simulation package dependencies

Usage

```
packages(sim, modules, paths, filenames, envir, clean = FALSE, ...)
```

```
## S4 method for signature 'ANY'
```

```
packages(sim, modules, paths, filenames, envir, clean = FALSE, ...)
```

Arguments

sim	A simList object.
modules	Character vector, specifying the name or vector of names of module(s)
paths	Character vector, specifying the name or vector of names of paths(s) for those modules. If path not specified, it will be taken from <code>getOption("spades.modulePath")</code> , which is set with <code>setPaths()</code>

filenames	Character vector specifying filenames of modules (i.e. combined path & module. If this is specified, then modules and path are ignored.
envir	Optional environment in which to store parsed code. This may be useful if the same file is being parsed multiple times. This function will check in that environment for the parsed file before parsing again. If the envir is transient, then this will have no effect.
clean	Optional logical. If TRUE, it will scrub any references to GitHub repositories, e.g., "PredictiveEcology/reproducible" will be returned as "reproducible".
...	All simInit parameters.

Value

A sorted character vector of package names.

Author(s)

Alex Chubaty & Eliot McIntire

See Also

Other functions to access elements of a 'simList' object: [.addDepends\(\)](#), [checkpointFile\(\)](#), [envir\(\)](#), [events\(\)](#), [globals\(\)](#), [inputs\(\)](#), [modules\(\)](#), [objs\(\)](#), [params\(\)](#), [paths\(\)](#), [progressInterval\(\)](#), [times\(\)](#)

paramCheckOtherMods	<i>Test and update a parameter against same parameter in other modules</i>
---------------------	--

Description

This function is intended to be part of module code and will test whether the value of a parameter within the current module matches the value of the same parameter in other modules. This is a test for parameters that might expect to be part of a `params = list(.globals = list(someParam = "test"))` passed to [simInit\(\)](#).

Usage

```
paramCheckOtherMods(
  sim,
  paramToCheck,
  moduleToUse = "all",
  ifSetButDifferent = c("error", "warning", "message", "silent"),
  verbose = getOption("reproducible.verbose")
)
```

Arguments

<code>sim</code>	A <code>simList</code> object
<code>paramToCheck</code>	A character string, length one, of a parameter name to check and compare between the current module and one or more or all others
<code>moduleToUse</code>	A character vector of module names to check against. This can be "all" which will compare against all other modules.
<code>ifSetButDifferent</code>	A character string indicating whether to "error" the default, or send a "warning", message or just silently continue (any other value).
<code>verbose</code>	Logical or Numeric, follows <code>reproducible.verbose</code> value by default.

Details

It is considered a "fail" under several conditions:

1. current module has a value that is not NULL or "default" and another module has a different value;
2. there is more than one value for the `paramToCheck` in the other modules, so it is ambiguous which one to return.

Either the current module is different than other modules, unless it is "default" or NULL.

Value

If the value of the `paramToCheck` in the current module is either NULL or "default", and there is only one other value across all modules named in `moduleToUse`, then this will return a character string with the value of the single parameter value in the other module(s). It will return the current value if there are no other modules with the same parameter.

params

Get and set simulation parameters

Description

`params`, `P` and `Par` (an active binding, like "mod") access the parameter slot in the `simList`. `params` has a `replace` method, so can be used to update a parameter value.

Usage

```
params(sim)

## S4 method for signature 'simList'
params(sim)

params(sim) <- value
```

```
## S4 replacement method for signature 'simList'
params(sim) <- value

P(sim, param, module)

P(sim, param, module) <- value

parameters(sim, asDF = FALSE)

## S4 method for signature 'simList'
parameters(sim, asDF = FALSE)
```

Arguments

sim	A simList object from which to extract element(s) or in which to replace element(s).
value	The parameter value to be set (in the corresponding module and param).
param	Optional character string indicating which parameter to choose.
module	Optional character string indicating which module params should come from.
asDF	Logical. For parameters, if TRUE, this will produce a single data.frame of all model parameters. If FALSE, then it will return a data.frame with 1 row for each parameter within nested lists, with the same structure as params.

Details

parameters will extract only the metadata with the metadata defaults, NOT the current values that may be overwritten by a user. See examples.

Value

Returns or sets the value of the slot from the simList object.

Note

The differences between P(), params() and being explicit with passing arguments are mostly a question of speed and code compactness. The computationally fastest way to get a parameter is to specify moduleName and parameter name, as in: P(sim, "paramName", "moduleName") (replacing moduleName and paramName with your specific module and parameter names), but it is more verbose than P(sim)\$paramName. Note: the important part for speed (e.g., 2-4x faster) is specifying the moduleName. Specifying the parameter name is <5% faster.

See Also

[SpaDES.core-package](#), specifically the section 1.2.1 on Simulation parameters.

Other functions to access elements of a 'simList' object: [.addDepends\(\)](#), [checkpointFile\(\)](#), [envir\(\)](#), [events\(\)](#), [globals\(\)](#), [inputs\(\)](#), [modules\(\)](#), [objs\(\)](#), [packages\(\)](#), [paths\(\)](#), [progressInterval\(\)](#), [times\(\)](#)

Examples

```
s <- simInit()
# add a parameter to tmp module
params(s)$tmp <- list(a = 1)

# Only work inside a module, inside a function with `sim` is an argument
# P(s, "a") # get "a" parameter inside the current module
# Par$a     # same. Get "a" parameter inside the current module

if (requireNamespace("NLMR", quietly = TRUE) &&
    requireNamespace("SpaDES.tools", quietly = TRUE)) {
  opts <- options("spades.moduleCodeChecks" = FALSE) # not necessary for example
  modules <- list("randomLandscapes")
  paths <- list(modulePath = getSampleModules(tempdir()))
  mySim <- simInit(modules = modules, paths = paths,
                  params = list(globals = list(stackName = "landscape")))

  # update some parameters using assignment -- currently only params will work
  params(mySim)$randomLandscapes$nx <- 200
  params(mySim)$randomLandscapes$ny <- 200

  parameters(mySim) # Does not contain these user overridden values

  # These next 2 are same here because they are not within a module
  P(mySim)          # Does contain the user overridden values
  params(mySim)     # Does contain the user overridden values

  # NOTE -- deleting a parameter will affect params and P, not parameters
  params(mySim)$randomLandscapes$nx <- NULL
  params(mySim)$randomLandscapes$ny <- NULL

  parameters(mySim) # Shows nx and ny

  # These next 2 are same here because they are not within a module
  P(mySim)          # nx and ny are Gone
  params(mySim)     # nx and ny are Gone

  options(opts) # reset
}
```

paths

Specify paths for modules, inputs, outputs, and temporary rasters

Description

Accessor functions for the paths slot in a `simList` object.

`dataPath` will return `file.path(modulePath(sim), currentModule(sim), "data")`. `dataPath`, like `currentModule`, is namespaced. This means that when it is used inside a module, then it will return *that model-specific* information. For instance, if used inside a module called "movingAgent",

then `currentModule(sim)` will return "movingAgent", and `dataPath(sim)` will return `file.path(modulePath(sim), "movingAgent", "data")`

Usage

```
paths(sim)

## S4 method for signature 'simList'
paths(sim)

paths(sim) <- value

## S4 replacement method for signature 'simList'
paths(sim) <- value

cachePath(sim)

## S4 method for signature 'simList'

terraPath(sim)

terraPath(sim) <- value

## S4 replacement method for signature 'simList'
terraPath(sim) <- value

dataPath(sim)
```

```
## S4 method for signature 'simList'
dataPath(sim)
```

Arguments

sim	A simList object from which to extract element(s) or in which to replace element(s).
value	The parameter value to be set (in the corresponding module and param).
module	The optional character string of the module(s) whose paths are desired. If omitted, will return all module paths, if more than one exist.

Details

These are ways to add or access the file paths used by [spades\(\)](#). There are five file paths: cachePath, modulePath, inputPath, outputPath, and rasterPath. Each has a function to get or set the value in a simList object. If no paths are specified, the defaults are as follows:

- cachePath: `getOption("reproducible.cachePath")`;
- inputPath: `getOption("spades.modulePath")`;
- modulePath: `getOption("spades.inputPath")`;
- outputPath: `getOption("spades.outputPath")`;
- rasterPath: `file.path(getOption("spades.scratchPath"), "raster")`;
- scratchPath: `getOption("spades.scratchPath")`;
- terraPath: `file.path(getOption("spades.scratchPath"), "terra")`

Value

Returns or sets the value of the slot from the simList object.

See Also

[SpaDES.core-package](#), specifically the section 1.2.4 on Simulation Paths.

Other functions to access elements of a 'simList' object: [.addDepends\(\)](#), [checkpointFile\(\)](#), [envir\(\)](#), [events\(\)](#), [globals\(\)](#), [inputs\(\)](#), [modules\(\)](#), [objs\(\)](#), [packages\(\)](#), [params\(\)](#), [progressInterval\(\)](#), [times\(\)](#)

Plot,simList-method *Plot method for simList objects*

Description

Extends `quickPlot::Plot` for simList objects.

Usage

```
## S4 method for signature 'simList'
Plot(
  ...,
  new = FALSE,
  addTo = NULL,
  gp = gpar(),
  gpText = gpar(),
  gpAxis = gpar(),
  axes = FALSE,
  speedup = 1,
  size = 5,
  cols = NULL,
  col = NULL,
  zoomExtent = NULL,
  visualSqueeze = NULL,
  legend = TRUE,
  legendRange = NULL,
  legendText = NULL,
  pch = 19,
  title = NULL,
  na.color = "#FFFFFF00",
  zero.color = NULL,
  length = NULL,
  arr = NULL,
  plotFn = "plot",
  verbose = getOption("quickPlot.verbose")
)
```

Arguments

...	A combination of spatialObjects or non-spatial objects. For many object classes, there are specific Plot methods. Where there are no specific ones, the base plotting will be used internally. This means that for objects with no specific Plot methods, many arguments, such as addTo, will not work. See details.
new	Logical. If TRUE, then the previous named plot area is wiped and a new one made; if FALSE, then the ... plots will be added to the current device, adding or rearranging the plot layout as necessary. Default is FALSE. This currently works best if there is only one object being plotted in a given Plot call. However, it is possible to pass a list of logicals to this, matching the length of the ... objects. Use clearPlot to clear the whole plotting device. NOTE if TRUE: <i>Everything that was there, including the legend and the end points of the colour palette, will be removed and re-initiated.</i>
addTo	Character vector, with same length as This is for overplotting, when the overplot is not to occur on the plot with the same name, such as plotting a SpatialPoints* object on a RasterLayer.
gp	A gpar object, created by <code>gpar()</code> , to change plotting parameters (see grid package).

gpText	A gpar object for the title text. Default <code>gpar(col = "black")</code> .
gpAxis	A gpar object for the axes. Default <code>gpar(col = "black")</code> .
axes	Logical or "L", representing the left and bottom axes, over all plots.
speedup	Numeric. The factor by which the number of pixels is divided by to plot rasters. See Details.
size	Numeric. The size, in points, for <code>SpatialPoints</code> symbols, if using a scalable symbol.
cols	(also <code>col</code>) Character vector or list of character vectors of colours. See details.
col	(also <code>cols</code>) Alternative to <code>cols</code> to be consistent with <code>plot</code> . <code>cols</code> takes precedence, if both are provided.
zoomExtent	An <code>Extent</code> object. Supplying a single extent that is smaller than the rasters will call a crop statement before plotting. Defaults to <code>NULL</code> . This occurs after any downsampling of rasters, so it may produce very pixelated maps.
visualSqueeze	Numeric. The proportion of the white space to be used for plots. Default is 0.75.
legend	Logical indicating whether a legend should be drawn. Default is <code>TRUE</code> .
legendRange	Numeric vector giving values that, representing the lower and upper bounds of a legend (i.e., <code>1:10</code> or <code>c(1,10)</code> will give same result) that will override the data bounds contained within the <code>grobToPlot</code> .
legendText	Character vector of legend value labels. Defaults to <code>NULL</code> , which results in a pretty numeric representation. If <code>Raster*</code> has a Raster Attribute Table (<code>rat</code> ; see raster package), this will be used by default. Currently, only a single vector is accepted. The length of this must match the length of the legend, so this is mostly useful for discrete-valued rasters.
pch	see <code>?par</code> .
title	Logical or character string. If logical, it indicates whether to print the object name as the title above the plot. If a character string, it will print this above the plot. NOTE: the object name is used with <code>addTo</code> , not the title. Default <code>NULL</code> , which means print the object name as title, if no other already exists on the plot, in which case, keep the previous title.
na.color	Character string indicating the colour for NA values. Default transparent.
zero.color	Character string indicating the colour for zero values, when zero is the minimum value, otherwise, zero is treated as any other colour. Default transparent.
length	Numeric. Optional length, in inches, of the arrow head.
arr	A vector of length 2 indicating a desired arrangement of plot areas indicating number of rows, number of columns. Default <code>NULL</code> , meaning let <code>Plot</code> function do it automatically.
plotFn	An optional function name to do the plotting internally, e.g., <code>"barplot"</code> to get a <code>barplot()</code> call. Default <code>"plot"</code> .
verbose	Numeric or logical. If <code>TRUE</code> or <code>>0</code> , then messages will be shown. If <code>FALSE</code> or <code>0</code> , most messages will be suppressed.

Details

See `quickPlot::Plot`. This method strips out stuff from a `simList` class object that would make it otherwise not reproducibly digestible between sessions, operating systems, or machines. This will likely still not allow identical digest results across R versions.

Value

invoked for side effect of plotting

`quickPlot::Plot`

Plots

Plot wrapper intended for use in a *SpaDES* module

Description

This is a single function call that allows a user to change which format in which the plots will occur. Specifically, the two common formats would be to "screen" or to disk as an image file, such as "png". *This has currently been tested with ggplot2, RasterLayer, and tmap objects.* The default (or change with e.g., `fn = "print"`, `usePlot = FALSE`) uses `Plot` internally, so individual plots may be rearranged. When saved to disk (e.g., via `type = 'png'`), then `Plot` will not be used and the single object that is the result of this `Plots` call will be saved to disk. This function requires at least 2 things: a plotting function and arguments passed to that function (which could include data, but commonly would simply be named arguments required by `fn`). See below and examples.

Usage

```
Plots(
  data,
  fn,
  filename,
  types = quote(params(sim)[[currentModule(sim)]]$.plots),
  path = quote(figurePath(sim)),
  .plotInitialTime = quote(params(sim)[[currentModule(sim)]]$.plotInitialTime),
  ggsaveArgs = list(),
  usePlot = getOption("spades.PlotsUsePlot", FALSE),
  deviceArgs = list(),
  ...
)
```

Arguments

<code>data</code>	An (optional) arbitrary data object. If supplied, it will be passed as the first argument to <code>Plot</code> function, and should contain all the data required for the inner plotting. If passing a <code>RasterLayer</code> , it may be a good idea to set <code>names(RasterLayer)</code> so that multiple layers can be plotted without overlapping each other. When a custom <code>fn</code> is used and all arguments for <code>fn</code> are supplied and named, then this can be omitted. See examples.
<code>fn</code>	An arbitrary plotting function. If not provided, defaults to using <code>quickPlot::Plot</code>
<code>filename</code>	A name that will be the base for the files that will be saved, i.e, do not supply the file extension, as this will be determined based on types. If a user provides this as an absolute path, it will override the <code>path</code> argument.
<code>types</code>	Character vector, zero or more of types. If used within a module, this will be deduced from the <code>P(sim)\$type</code> and can be omitted. See below.
<code>path</code>	Currently a single path for the saved objects on disk. If <code>filename</code> is supplied as an absolute path, <code>path</code> will be set to <code>dirname(filename)</code> , overriding this argument value.
<code>.plotInitialTime</code>	A numeric. If <code>NA</code> then no visual on screen. Anything else will have visuals plotted to screen device. This is here for backwards compatibility. A developer should set in the module to the intended initial plot time and leave it, i.e., <i>not</i> <code>NA</code> .
<code>ggsaveArgs</code>	An optional list of arguments passed to <code>ggplot2::ggsave</code>
<code>usePlot</code>	Logical. If <code>TRUE</code> , the default, then the plot will occur with <code>quickPlot::Plot</code> , so it will be arranged with previously existing plots.
<code>deviceArgs</code>	An optional list of arguments passed to one of <code>png</code> , <code>pdf</code> , <code>tiff</code> , <code>bmp</code> , or <code>jpeg</code> . This is useful when the plotting function is not creating a <code>ggplot</code> object, e.g., plotting a <code>RasterLayer</code> .
<code>...</code>	Anything needed by <code>fn</code> , all named.

Details

- `type`
 - `"screen"` – Will plot to the current device, normally a plot window
 - `"object"` – Will save the plot object, e.g., `ggplot` object
 - `"raw"` – Will save the raw data prior to plotting, e.g., the data argument
 - `"png"` – or any other type save-able with `ggsave`

Value

Called for its side effect of plot creation.

Recording of files saved

In cases where files are saved, and where `Plots` is used within a `SpaDES` module, the file(s) that is/are saved will be appended to the `outputs` slot of the `simList` of the module. This will, therefore, keep a record of figures saved *within* the `simList`

Note

This is still experimental and could change in the next release.

Plots now has experimental support for "just a Plot call", but with types specified. See examples. The devices to save on disk will have some different behaviours to the screen representation, since "wiping" an individual plot on a device doesn't exist for a file device.

This offers up to 4 different actions for a given plot:

- To screen device
- To disk as raw data (limited testing)
- To disk as a saved plot object (limited testing)
- To disk as a '.png' or other image file, e.g., '.pdf'

To turn off plotting both to screen and disk, set both `.plotInitialTime = NA` and `.plots = NA` or any other value that will not trigger a TRUE with a `grepl` with the `types` argument (e.g., "" will omit all saving).

Examples

```
# Note: if this is used inside a SpaDES module, do not define this
# function inside another function. Put it outside in a normal
# module script. Otherwise, it will cause a memory leak.
if (requireNamespace("ggplot2")) {
  fn <- function(d)
    ggplot2::ggplot(d, ggplot2::aes(a)) +
    ggplot2::geom_histogram()
  sim <- simInit()
  sim$something <- data.frame(a = sample(1:10, replace = TRUE))

  Plots(data = sim$something, fn = fn,
        types = c("png"),
        path = file.path("figures"),
        filename = tempfile(),
        .plotInitialTime = 1
        )

  # plot to active device and to png
  Plots(data = sim$something, fn = fn,
        types = c("png", "screen"),
        path = file.path("figures"),
        filename = tempfile(),
        .plotInitialTime = 1
        )

  # Can also be used like quickPlot::Plot, but with control over output type
  r <- terra::rast(terra::ext(0,10,0,10), vals = sample(1:3, size = 100, replace = TRUE))
  Plots(r, types = c("screen", "png"), deviceArgs = list(width = 700, height = 500),
        usePlot = TRUE)

  # with ggplotify, Plots can also be used to plot/save
  # non-ggplot objects:
```

```
if (require("ggplotify")) {  
  if (!require("lattice")) stop("please install lattice")  
  
  plotFile <- tempfile()  
  
  p1 <- densityplot(~mpg|cyl, data=mtcars)  
  Plots(data = p1, fn = as.ggplot, filename = plotFile,  
        ggsaveArgs = list(width = 5, height = 4, dpi = 300, bg = "white", units = "in"),  
        types = c("screen", "png"), .plotInitialTime = 1)  
}  
} # end ggplot  
# end of dontrun
```

priority

Event priority

Description

Preset event priorities: 1 = first (highest); 5 = normal; 10 = last (lowest).

Usage

```
.first()  
  
.highest()  
  
.last()  
  
.lowest()  
  
.normal()
```

Value

numeric of length 1.

Author(s)

Alex Chubaty

progressInterval	<i>Get and set simulation progress bar details</i>
------------------	--

Description

The progress bar can be set in two ways in SpaDES. First, by setting values in the `.progress` list element in the `params` list element passed to `simInit()`. Second, at the `spades()` call itself, which can be simpler. See examples.

Usage

```
progressInterval(sim)

## S4 method for signature 'simList'
progressInterval(sim)

progressInterval(sim) <- value

## S4 replacement method for signature 'simList'
progressInterval(sim) <- value

progressType(sim)

## S4 method for signature 'simList'
progressType(sim)

progressType(sim) <- value

## S4 replacement method for signature 'simList'
progressType(sim) <- value
```

Arguments

<code>sim</code>	A <code>simList</code> object from which to extract element(s) or in which to replace element(s).
<code>value</code>	The parameter value to be set (in the corresponding module and param).

Details

Progress Bar: Progress type can be one of "text", "graphical", or "shiny". Progress interval can be a numeric. These both can get set by passing a `.progress = list(type = "graphical", interval = 1)` into the `simInit` call. See examples.

Value

for `progressInterval`, a numeric corresponding to the progress update interval; for `progressInterval<-`, an updated `simList` object.

See Also

Other functions to access elements of a 'simList' object: `.addDepends()`, `checkpointFile()`, `envir()`, `events()`, `globals()`, `inputs()`, `modules()`, `objs()`, `packages()`, `params()`, `paths()`, `times()`

Examples

```
if (requireNamespace("SpaDES.tools", quietly = TRUE) &&
    requireNamespace("NLMR", quietly = TRUE)) {
  opts <- options("spades.moduleCodeChecks" = FALSE) # not necessary for example
  mySim <- simInit(
    times = list(start=0.0, end=100.0),
    params = list(.globals = list(stackName = "landscape"),
      .progress = list(type = "text", interval = 10),
      checkpoint = list(interval = 10, file = "chkpnt.RData")),
    modules = list("randomLandscapes"),
    paths = list(modulePath = getSampleModules(tempdir()))
  )

  # progress bar
  progressType(mySim) # "text"
  progressInterval(mySim) # 10

  # parameters
  params(mySim) # returns all parameters in all modules
                # including .global, .progress, checkpoint
  globals(mySim) # returns only global parameters

  # checkpoint
  checkpointFile(mySim) # returns the name of the checkpoint file
                        # In this example, "chkpnt.RData"
  checkpointInterval(mySim) # 10

  options(opts) # reset
}
```

rasterCreate

Simple wrapper to load any Raster object*

Description

This wraps either `raster::raster`, `raster::stack`, `raster::brick`, or `terra::rast`, allowing a single function to be used to create a new object of the same class as a template. This works for all `Raster*` and `SpatRaster` class templates.

Usage

```
rasterCreate(x, ...)
```

```
## Default S3 method:
rasterCreate(x, ...)
```

Arguments

<code>x</code>	An object, notably a <code>Raster*</code> object. All others will simply be passed through with no effect.
<code>...</code>	Passed to <code>raster::raster</code> , <code>raster::stack</code> , or <code>raster::brick</code>

Value

a new (empty) object of same class as the original.

Methods (by class)

- `rasterCreate(default)`: Simply passes through argument with no effect

<code>rasterToMemory</code>	<i>Read raster to memory</i>
-----------------------------	------------------------------

Description

Wrapper to the `raster` function, that creates the raster object in memory, even if it was read in from file. There is the default method which is just a pass through, so this can be safely used on large complex objects, recursively, e.g., a `simList`.

Usage

```
rasterToMemory(x, ...)

## S4 method for signature 'list'
rasterToMemory(x, ...)

## S4 method for signature 'character'
rasterToMemory(x, ...)

## S4 method for signature 'ANY'
rasterToMemory(x, ...)

## S4 method for signature 'simList'
rasterToMemory(x, ...)
```

Arguments

<code>x</code>	An object passed directly to the function <code>raster</code> (e.g., character string of a file-name).
<code>...</code>	Additional arguments to <code>raster::raster</code> , <code>raster::stack</code> , or <code>raster::brick</code> .

Value

A raster object whose values are stored in memory.

Author(s)

Eliot McIntire and Alex Chubaty

See Also

`raster()`, [terra::rast\(\)](#).

`remoteFileSize`*Determine the size of a remotely hosted file*

Description

Defunct. Will be removed by mid-2023.

Usage

```
remoteFileSize(url)
```

Arguments

`url` The url of the remote file.

Value

A numeric indicating the size of the remote file in bytes.

Author(s)

Eliot McIntire and Alex Chubaty

restartR

*Restart R programmatically***Description**

This will attempt to restart the R session, reloading all packages, and saving and reloading the `simList`. Currently, this is not intended for general use: it has many specialized pieces for using inside a `spades` call. The main purpose for doing this is to clear memory leaks (possibly deep in R <https://github.com/r-lib/fastmap>) that are not fully diagnosed. *This is still very experimental.* This should only be used if there are RAM limitations being hit with long running simulations. It has been tested to work Linux within Rstudio and at a terminal R session. The way to initiate restarting of R is simply setting the `spades.restartRInterval` or setting the equivalent parameter in the `restartR` core module via: `simInit(..., params = list(.restartR = list(.restartRInterval = 1)), ...)` greater than 0, which is the default, e.g., `options("spades.restartRInterval" = 100)`. This is only intended to restart a simulation in exactly the same place as it was (i.e., cannot change machines), and because of the restart, the assignment of the `spades` call will be either to `sim` or the user must make such an assignment manually, e.g., `sim <- savedSimEnv()$.sim`, or perhaps, the safer `sim <- Copy(savedSimEnv()$.sim)`. This is stated in a message.

Usage

```
restartR(
  sim,
  reloadPkgs = TRUE,
  .First = NULL,
  .RDataFile = getOption("spades.restartR.RDataFilename"),
  restartDir = getOption("spades.restartR.restartDir", NULL)
)
```

Arguments

<code>sim</code>	Required. A <code>simList</code> to be retained through the restart
<code>reloadPkgs</code>	Logical. If <code>TRUE</code> , it will attempt to reload all the packages as they were in previous session, in the same order. If <code>FALSE</code> , it will load no packages beyond normal R startup. Default <code>TRUE</code>
<code>.First</code>	A function to save to <code>'~/ .qs'</code> which will be loaded at restart from <code>'~/ .qs'</code> and run. Default is <code>NULL</code> , meaning it will use the non-exported <code>SpaDES.core:::First</code> . If a user wants to make a custom <code>First</code> file, it should built off that one.
<code>.RDataFile</code>	A filename for saving the <code>simList</code> . Defaults to <code>getOption("spades.restartR.filename")</code> , and the directory will be in <code>restartDir</code> . The simulation time will be mid-pended to this name, as in: <code>basename(file), "_time", paddedFloatToChar(time(sim), padL = nchar(</code>
<code>restartDir</code>	A character string indicating root directory to save <code>simList</code> and other ancillary files during restart. Defaults to <code>getOption("spades.restartR.restartDir", NULL)</code> . If <code>NULL</code> , then it will try, in order, <code>outputPath(sim)</code> , <code>modulePath(sim)</code> , <code>inputPath(sim)</code> , <code>cachePath(sim)</code> , taking the first one that is not inside the <code>tempdir()</code> , which will disappear during restart of R. The actual directory for a

given spades call that is restarting will be: `file.path(restartDir, "restartR", paste0(sim$._startClockTime, "_", .rndString))`. The random string is to prevent parallel processes that started at the same clock time from colliding.

Details

The process responds to several options. Though under most cases, the default behaviour should suffice. These are of 3 types: `restartRInterval` the arguments to `restartR` and the arguments to `saveSimList`, these latter two using a dot to separate the function name and its argument. The defaults for two key options are: `options("spades.restartR.restartDir" = NULL, meaning use file.path(restartDir, "restartR", paste0(sim$._startClockTime, "_", .rndString)) and options("spades.saveSimList.fileBackend" = 0), which means don't do anything with raster-backed files. See specific functions for defaults and argument meanings. The only difference from the default function values is with saveSimList argument fileBackend = FALSE during restartR by default, because it is assumed that the file backends will still be intact after a restart, so no need to move them all to memory.`

Value

invoked for side effect of restarting the R session

Note

Because of the restarting, the object name of the original assignment of the spades call can not be preserved. The spades call will be assigned to `sim` in the `.GlobalEnv`.

Because this function is focused on restarting during a spades call, it will remove all objects in the `.GlobalEnv`, emulating `q("no")`. If the user wants to keep those objects, then they should be saved to disk immediately before the spades call. This can then be recovered immediately after the return from the spades call.

To keep the saved `simList`, use `options("spades.restartR.clearFiles" = TRUE)`. The default is to treat these files as temporary files and so will be removed.

restartSpades

Restart an interrupted simulation

Description

This is very experimental and has not been thoroughly tested. Use with caution. This function will re-parse a single module (currently) into the `simList` where its source code should reside, and then optionally restart a simulation that stopped on an error, presumably after the developer has modified the source code of the module that caused the break. This will restart the simulation at the next event in the event queue (i.e., returned by `events(sim)`). Because of this, this function will not do anything if the event queue is empty.

Usage

```
restartSpades(sim = NULL, module = NULL, numEvents = Inf, restart = TRUE, ...)
```

Arguments

sim	A simList. If not supplied (the default), this will take the sim from savedSimEnv()\$.sim, i.e., the one that was interrupted
module	A character string length one naming the module that caused the error and whose source code was fixed. This module will be re-parsed and placed into the simList
numEvents	Numeric. Default is Inf (i.e., all available). In the simList, if options('spades.recoveryMode') is set to TRUE or a numeric, then there will be a list in the simList called .recoverableObjs. These will be replayed backwards in time to reproduce the initial state of the simList before the event that is numEvents back from the first event in events(sim).
restart	Logical. If TRUE, then the call to spades will be made, i.e., restarting the simulation. If FALSE, then it will return a new simList with the module code parsed into the simList
...	Passed to spades, e.g., debug, .plotInitialTime

Details

This will only parse the source code from the named module. It will not affect any objects that are in the mod or sim.

The random number seed will be reset to the state it was at the start of the earliest event recovered, thereby returning to the exact stochastic simulation trajectory.

Value

A simList as if spades had been called on a simList.

Note

This will only work reliably *if the simList was not modified yet during the event which caused the error*. The simList will be in the state it was at the time of the error.

Examples

```
# options("spades.recoveryMode" = 1) # now the default
s <- simInit()
s <- spades(s) # if this is interrupted or fails
# the following line will not work if the previous line didn't fail
s <- restartSpades(s) # don't need to specify `sim` if previous line fails
# will take from savedSimEnv()$.sim automatically
```

savedSimEnv	<i>Retrieve environment for saving interrupted simulations</i>
-------------	--

Description

If the user sets `options(reproducible.memoisePersist = TRUE)`, the global environment will be used, otherwise, a package environment.

Usage

```
savedSimEnv(envir = .GlobalEnv)
```

Arguments

envir	an environment to use to store the <code>.sim</code> (<code>simList</code>) object. default is to use the user's global environment (<code>.GlobalEnv</code>).
-------	--

saveFiles	<i>Save objects using <code>.saveObjects</code> in params slot of <code>simInit</code></i>
-----------	--

Description

In the `simInit()` call, a parameter called `.saveObjects` can be provided in each module. This must be a character string vector of all object names to save. These objects will then be saved whenever a call to `saveFiles` is made.

Usage

```
saveFiles(sim)
```

Arguments

sim	A <code>simList</code> simulation object.
-----	---

Details

The file names will be equal to the object name plus `time(sim)` is appended at the end. The files are saved as `.rds` files, meaning, only one object gets saved per file.

For objects saved using this function, the module developer must create save events that schedule a call to `saveFiles`.

If this function is used outside of a module, it will save all files in the `outputs(sim)` that are scheduled to be saved at the current time in the `simList`.

There are several ways to save objects using SpaDES.

Value

(invisibly) the modified sim object. invoked for side effect of saving the simulation to file.

Model-level saving

Using the outputs slot in the `simInit()` call. See example in `simInit()`. This can be convenient because it gives overall control of many modules at a time, and it gets automatically scheduled during the `simInit()` call.

Module-level saving

Using the `saveFiles` function inside a module. This must be accompanied by a `.saveObjects` vector or list element in the `params` slot in the `simList()`. Usually a module developer will create this method for future users of their module.

Custom saving

A module developer can save any object at any time inside their module, using standard R functions for saving R objects (e.g., `save` or `saveRDS`). This is the least modular approach, as it will happen whether a module user wants it or not.

Note

It is not possible to schedule separate saving events for each object that is listed in the `.saveObjects`.

Author(s)

Eliot McIntire and Alex Chubaty

Examples

```
if (requireNamespace("SpaDES.tools", quietly = TRUE) &&
    requireNamespace("NLMR", quietly = TRUE)) {
  ## This will save the "caribou" object at the save interval of 1 unit of time
  ## in the outputPath location
  outputPath <- file.path(tempdir(), "test_save")
  times <- list(start = 0, end = 1, "month")

  modules <- list("randomLandscapes", "caribouMovement")
  paths <- list(
    modulePath = getSampleModules(tempdir()),
    outputPath = outputPath
  )
  opts <- options("spades.moduleCodeChecks" = FALSE,
                  "spades.useRequire" = FALSE) # not necessary for example

  ## save multiple outputs
  parameters <- list(
    .globals = list(stackName = "landscape"),
    caribouMovement = list(
      .saveObjects = c("caribou", "habitatQuality"),
```

```

        .saveInitialTime = 1, .saveInterval = 1
    ),
    randomLandscapes = list(.plots = NA, nx = 20, ny = 20))

mySim <- simInit(times = times, params = parameters, modules = modules,
                paths = paths)

spades(mySim, .plotInitialTime = NA) # plotting not relevant for this example
dir(outputPath)
# remove the files
file.remove(dir(outputPath, full.names = TRUE))

options(opts) # clean up
}

```

saveSimList

Save a whole simList object to disk

Description

Saving a `simList` may not work using the standard approaches (e.g., `save`, `saveRDS`, and `qs::qsave`). There are 2 primary reasons why this doesn't work as expected: the `activeBindings` that are in place within modules (these allow the `mod` and `Par` to exist), and file-backed objects, such as `SpatRaster` and `Raster*`. Because of these, a user should use `saveSimList` and `loadSimList`. These will save the object and recover the object using the filename supplied, if there are no file-backed objects. If there are file-backed objects, then it will save an archive (default is `.tar.gz` using the `archive` package for non-Windows and `zip()` if using Windows, as there is currently an unidentified bug in `archive*` on Windows). The user does not need to specify the filename any differently, as the code will search based on the filename without the file extension.

Usage

```

saveSimList(
  sim,
  filename,
  projectPath = getwd(),
  outputs = TRUE,
  inputs = TRUE,
  cache = FALSE,
  envir,
  ...
)

```

Arguments

<code>sim</code>	Either a <code>simList</code> or a character string of the name of a <code>simList</code> that can be found in <code>envir</code> . Using a character string will assign that object name to the saved <code>simList</code> , so when it is recovered it will be given that name.
------------------	---

filename	Character string with the path for saving simList to or reading the simList from. Currently, only .rds and .qs file types are supported.
projectPath	Should be the "top level" or project path for the simList. Defaults to getwd(). All other paths will be made relative with respect to this if nested within this.
outputs	Logical. If TRUE, all files identified in outputs(sim) will be included in the zip.
inputs	Logical. If TRUE, all files identified in inputs(sim) will be included in the zip.
cache	Logical. Not yet implemented. If TRUE, all files in cachePath(sim) will be included in the archive. Defaults to FALSE as this could be large, and may include many out of date elements. See Details.
envir	If sim is a character string, then this must be provided. It is the environment where the object named sim can be found.
...	Additional arguments. See Details.

Details

There is a family of 2 functions that are mutually useful for saving and loading simList objects and their associated files (e.g., file-backed Raster*, inputs, outputs, cache) [saveSimList\(\)](#), [loadSimList\(\)](#).

Additional arguments may be passed via ..., including:

- files: logical indicating whether files should be included in the archive. if FALSE, will override cache, inputs, outputs, setting them to FALSE.
- symlinks: a named list of paths corresponding to symlinks, which will be used to substitute normalized absolute paths of files. Names should correspond to the names in paths(); values should be project-relative paths. E.g., list(cachePath = "cache", inputPath = "inputs", outputPath = "outputs").

Value

Invoked for side effects of saving both a .qs (or .rds) file, and a compressed archive (one of .tar.gz if using non-Windows OS or .zip on Windows).

See Also

[loadSimList\(\)](#)

scheduleConditionalEvent

Schedule a conditional simulation event

Description

Adds a new event to the simulation's conditional event queue, updating the simulation object by creating or appending to sim\$._conditionalEvents. *This is very experimental. Use with caution.*

Usage

```

scheduleConditionalEvent(
  sim,
  condition,
  moduleName,
  eventType,
  eventPriority = .normal(),
  minEventTime = start(sim),
  maxEventTime = end(sim)
)

```

Arguments

sim	A simList simulation object.
condition	A string, call or expression that will be assessed for TRUE after each event in the regular event queue. It can access objects in the simList by using functions of sim, e.g., "sim\$age > 1"
moduleName	A character string specifying the module from which to call the event. If missing, it will use currentModule(sim)
eventType	A character string specifying the type of event from within the module.
eventPriority	A numeric specifying the priority of the event. Lower number means higher priority. As a best practice, it is recommended that decimal values are conceptual grouped by their integer values (e.g., 4.0, 4.25, 4.5 are conceptually similar). See priority() .
minEventTime	A numeric specifying the time before which the event should not occur, even if the condition is met. Defaults to start(sim)
maxEventTime	A numeric specifying the time after which the event should not occur, even if the condition is met. Defaults to end(sim)

Details

This conditional event queue will be assessed at every single event in the normal event queue. If there are no conditional events, then spades will proceed as normal. As conditional event conditions are found to be true, then it will trigger a call to `scheduleEvent(...)` with the current time passed to `eventTime` *and* it will remove the conditional event from the conditional queue. If the user would like the triggered conditional event to occur as the very next event, then a possible strategy would be to set `eventPriority` of the conditional event to very low or even negative to ensure it gets inserted at the top of the event queue.

Value

Returns the modified simList object, i.e., `sim$._conditionalEvents`.

Examples

```
sim <- simInit(times = list(start = 0, end = 2))
condition <- "sim$age > 1" # provide as string
condition <- quote(sim$age > 1) # provide as a call
condition <- expression(sim$age > 1) # provide as an expression
sim <- scheduleConditionalEvent(sim, condition, "firemodule", "burn")
conditionalEvents(sim)
sim <- spades(sim) # no changes to sim$age, i.e., it is absent
events(sim) # nothing scheduled
sim$age <- 2 # change the value
sim <- spades(sim) # Run spades, the condition is now true, so event is
                  # scheduled at current time
events(sim)       # now scheduled in the normal event queue
```

scheduleEvent

Schedule a simulation event

Description

Adds a new event to the simulation's event queue, updating the simulation object.

Usage

```
scheduleEvent(
  sim,
  eventTime,
  moduleName,
  eventType,
  eventPriority = .pkgEnv$.normalVal,
  .skipChecks = FALSE
)
```

Arguments

sim	A <code>simList</code> simulation object.
eventTime	A numeric specifying the time of the next event.
moduleName	A character string specifying the module from which to call the event. If missing, it will use <code>currentModule(sim)</code>

eventType	A character string specifying the type of event from within the module.
eventPriority	A numeric specifying the priority of the event. Lower number means higher priority. As a best practice, it is recommended that decimal values are conceptual grouped by their integer values (e.g., 4.0, 4.25, 4.5 are conceptually similar). See priority() .
.skipChecks	Logical. If TRUE, then internal checks that arguments match expected types are skipped. Should only be used if speed is critical.

Details

Here, we implement a simulation in a more modular fashion so it's easier to add submodules to the simulation. We use S4 classes and methods, and use `data.table` instead of `data.frame` to implement the event queue (because it is much faster).

Value

Returns the modified `simList` object.

Examples

```
sim <- simInit()
sim <- scheduleEvent(sim, time(sim) + 1.0, "fireSpread", "burn") # default priority
sim <- scheduleEvent(sim, time(sim) + 1.0, "fireSpread", "burn", .normal()) # default priority

sim <- scheduleEvent(sim, time(sim) + 1.0, "fireSpread", "burn", .normal()-1) # higher priority
sim <- scheduleEvent(sim, time(sim) + 1.0, "fireSpread", "burn", .normal()+1) # lower priority

sim <- scheduleEvent(sim, time(sim) + 1.0, "fireSpread", "burn", .highest()) # highest priority
sim <- scheduleEvent(sim, time(sim) + 1.0, "fireSpread", "burn", .lowest()) # lowest priority
events(sim) # shows all scheduled events, with eventTime and priority
```

show,simList-method	<i>Show an Object</i>
---------------------	-----------------------

Description

Show an Object

Usage

```
## S4 method for signature 'simList'
show(object)
```

Arguments

object simList

Author(s)

Alex Chubaty

simFile	<i>Generate simulation file name</i>
---------	--------------------------------------

Description

Assists with saving and retrieving simulations (e.g., with saveSimList and loadSimList).

Usage

```
simFile(name, path, time = NULL, ext = "rds")
```

Arguments

name	Object name (e.g., "mySimOut")
path	Directory location in where the file will be located (e.g., an outputPath).
time	Optional simulation time to use as filename suffix. Default NULL.
ext	The file extension to use (default "rds").

Value

character string giving a file path for a simulation file

`simInit`*Initialize a new simulation*

Description

Create a new simulation object, the `sim` object (a `simList`). This object is implemented using an environment where all objects and functions are placed. Since environments in R are pass by reference, "putting" objects in the `sim` object does no actual copy. The `simList` also stores all parameters, and other important simulation information, such as times, paths, modules, and module load order. See more details below.

Usage

```
simInit(  
  times,  
  params,  
  modules,  
  objects,  
  paths,  
  inputs,  
  outputs,  
  loadOrder,  
  notOlderThan = NULL,  
  ...  
)  
  
## S4 method for signature  
## 'list,list,list,list,list,data.frame,data.frame,character'  
simInit(  
  times,  
  params,  
  modules,  
  objects,  
  paths,  
  inputs,  
  outputs,  
  loadOrder,  
  notOlderThan = NULL,  
  ...  
)  
  
## S4 method for signature 'ANY,ANY,ANY,character,ANY,ANY,ANY,ANY'  
simInit(  
  times,  
  params,  
  modules,  
  objects,
```

```

    paths,
    inputs,
    outputs,
    loadOrder,
    notOlderThan = NULL,
    ...
)

## S4 method for signature 'ANY,ANY,character,ANY,ANY,ANY,ANY,ANY'
simInit(
  times,
  params,
  modules,
  objects,
  paths,
  inputs,
  outputs,
  loadOrder,
  notOlderThan = NULL,
  ...
)

## S4 method for signature 'ANY,ANY,ANY,ANY,ANY,ANY,ANY,ANY'
simInit(
  times,
  params,
  modules,
  objects,
  paths,
  inputs,
  outputs,
  loadOrder,
  notOlderThan = NULL,
  ...
)

simInitDefaults()

```

Arguments

times	A named list of numeric simulation start and end times (e.g., <code>times = list(start = 0.0, end = 10.0, timeunit = "year")</code>), with the final optional element, <code>timeunit</code> , overriding the default time unit used in the simulation which is the "smallest time unit" across all modules. See examples.
params	A list of lists of the form <code>list(moduleName=list(param1=value, param2=value))</code> . See details.
modules	A named list of character strings specifying the names of modules to be loaded for the simulation. Note: the module name should correspond to the R source

file from which the module is loaded. Example: a module named "caribou" will be sourced from the file 'caribou.R', located at the specified `modulePath(simList)` (see below).

objects	(optional) A vector of object names (naming objects that are in the calling environment of the <code>simInit</code> , which is often the <code>.GlobalEnv</code> unless used programmatically. NOTE: this mechanism will fail if object name is in a package dependency), or a named list of data objects to be passed into the <code>simList</code> (more reliable). These objects will be accessible from the <code>simList</code> as a normal list, e.g., <code>mySim\$obj</code> .
paths	An optional named list with up to 4 named elements, <code>modulePath</code> , <code>inputPath</code> , <code>outputPath</code> , and <code>cachePath</code> . See details. NOTE: Experimental feature now allows for multiple <code>modulePaths</code> to be specified in a character vector. The modules will be searched for sequentially in the first <code>modulePath</code> , then if it doesn't find it, in the second etc.
inputs	A data.frame. Can specify from 1 to 6 columns with following column names: <code>objectName</code> (character, required), <code>file</code> (character), <code>fun</code> (character), <code>package</code> (character), <code>interval</code> (numeric), <code>loadTime</code> (numeric). See <code>inputs()</code> and vignette("ii-modules") section about inputs.
outputs	A data.frame. Can specify from 1 to 5 columns with following column names: <code>objectName</code> (character, required), <code>file</code> (character), <code>fun</code> (character), <code>package</code> (character), <code>saveTime</code> (numeric) and <code>eventPriority</code> (numeric). If <code>eventPriority</code> is not set, it defaults to <code>.last()</code> . If <code>eventPriority</code> is set to a low value, e.g., 0, 1, 2 and <code>saveTime</code> is <code>start(sim)</code> , it should give "initial conditions". See <code>outputs()</code> and vignette("ii-modules") section about outputs.
loadOrder	An optional character vector of module names specifying the order in which to load the modules. If not specified, the module load order will be determined automatically.
notOlderThan	A time, as in from <code>Sys.time()</code> . This is passed into the <code>Cache</code> function that wraps <code>.inputObjects</code> . If the module uses the <code>.useCache</code> parameter and it is set to <code>TRUE</code> or <code>".inputObjects"</code> , then the <code>.inputObjects</code> will be cached. Setting <code>notOlderThan = Sys.time()</code> will cause the cached versions of <code>.inputObjects</code> to be refreshed, i.e., rerun.
...	An alternative way to pass objects, i.e., they can just be named arguments rather than in a <code>objects = list(...)</code> . It can also be any options that begins with <code>spades</code> , <code>reproducible</code> or <code>Require</code> , i.e., those identified in <code>spadesOptions()</code> , <code>reproducibleOptions()</code> or <code>RequireOptions()</code> . These will be assigned to the equivalent option <i>during</i> the <code>simInit</code> and <code>spades</code> calls only, i.e., they will revert after the <code>simInit</code> or <code>spades</code> calls are complete. NOTE: these are not passed to the <code>simList</code> per se, i.e., they are not be available in the <code>simList</code> during either the <code>simInit</code> or <code>spades</code> calls via <code>sim\$xxx</code> , though they will be returned to the <code>simList</code> at the end of each of these calls (so that the next call to e.g., <code>spades</code> can see them). For convenience, these can be supplied without their package prefix, e.g., <code>lowMemory</code> can be specified instead of <code>spades.lowMemory</code> . In cases that share option name (<code>reproducible.verbose</code> and <code>Require.verbose</code> both exist), passing <code>verbose = FALSE</code> will set both. Obviously this may cause unexpected problems if a module is also expecting a value.

Details

Calling this simInit function does the following::

What	Details
fills simList slots	places the arguments times, params, modules, paths into equivalently named simList slots
sources all module files	places all function definitions in the simList, specifically, into a sub-environment of the module environment
copies objects	from the global environment to the simList environment
loads objects	from disk into the simList
schedule object loading/copying	Objects can be loaded into the simList at any time during a simulation
schedule object saving	Objects can be saved to disk at any arbitrary time during the simulation. If specified here, the objects are saved
schedules "init" events	from all modules (see events())
assesses module dependencies	via the inputs and outputs identified in their metadata. This gives the order of the .inputObjects
determines time unit	takes time units of modules and how they fit together
runs .inputObjects functions	from every module <i>in the module order as determined above</i>

params can only contain updates to any parameters that are defined in the metadata of modules.

Take the example of a module named, Fire, which has a parameter named .plotInitialTime. In

the metadata of that module, it says TRUE. Here we can override that default with: `list(Fire=list(.plotInitialTime=NA))`

effectively turning off plotting. Since this is a list of lists, one can override the module defaults for

multiple parameters from multiple modules all at once, with say: `list(Fire = list(.plotInitialTime`

`= NA, .plotInterval = 2), caribouModule = list(N = 1000))`.

The params list can contain a list (named .globals) of named objects e.g., `.globals = list(climateURL`

`= "https:\\something.com")` entry. Any and every module that has a parameter with that name

(in this case climateURL) will be overridden with this value as passed.

params can be used to set the seed for a specific event in a module. This is done using the normal

params argument, specifying .seed as a list where the elements are a numeric for the seed and the

name is the event. Since parameters must be specific to a module, this creates a module and event

specific seed e.g., `params = list(moduleName = list(.seed = list(init = 123)))` will set the

init event of module named moduleName to 123. The RN stream will be reset to its state prior to

the `set.seed` call after the event.

We implement a discrete event simulation in a more modular fashion so it is easier to add modules

to the simulation. We use S4 classes and methods, and fast lists to manage the event queue.

paths specifies the location of the module source files, the data input files, and the saving output

files. If no paths are specified the defaults are as follows:

- `cachePath: getOption("reproducible.cachePath");`
- `inputPath: getOption("spades.inputPath");`
- `modulePath: getOption("spades.modulePath");`
- `outputPath: getOption("spades.outputPath");`

Value

A simList simulation object, pre-initialized from values specified in the arguments supplied.

Parsing and Checking Code

The `simInit` function will attempt to find usage of `sim$xxx` or `sim[['xxx']]` on either side of the assignment (`<-`) operator. It will compare these to the module metadata, specifically `inputObjects` for cases where objects or "gotten" from the `simList` and `outputObjects` for cases where objects are assigned to the `simList`.

It will also attempt to find potential, common function name conflicts with things like `scale` and `stack` (both in **base** and **raster**), and `Plot` (in **quickPlot** and some modules).

This code checking is young and may get false positives and false negatives, i.e., miss things. It also takes computational time, which may be undesirable in operational code. To turn off checking (i.e., if there are too many false positives and negatives), set `options(spades.moduleCodeChecks = FALSE)`.

Caching

Using caching with SpaDES is vital when building re-usable and reproducible content. Please see the vignette dedicated to this topic.

Note

Since the objects in the `simList` are passed-by-reference, it is useful to create a copy of the initialized `simList` object prior to running the simulation (e.g., `mySimOut <- spades(Copy(mySim))`). This ensures you retain access to the original objects, which would otherwise be overwritten/modified during the simulation.

The user can opt to run a simpler `simInit` call without inputs, outputs, and times. These can be added later with the accessor methods (See example). These are not required for initializing the simulation via `simInit`. All of modules, paths, params, and objects are needed for successful initialization.

Description

These functions are convenience wrappers that may allow for more efficient caching. Passes all arguments to `simInit()`, then passes the created `simList` to `spades()`.

Usage

```
simInitAndSpades(
  times,
  params,
  modules,
  objects,
  paths,
  inputs,
  outputs,
  loadOrder,
  notOlderThan,
  debug,
  progress,
  cache,
  .plots,
  .plotInitialTime,
  .saveInitialTime,
  events,
  ...
)
```

Arguments

<code>times</code>	A named list of numeric simulation start and end times (e.g., <code>times = list(start = 0.0, end = 10.0, timeunit = "year")</code>), with the final optional element, <code>timeunit</code> , overriding the default time unit used in the simulation which is the "smallest time unit" across all modules. See examples.
<code>params</code>	A list of lists of the form <code>list(moduleName=list(param1=value, param2=value))</code> . See details.
<code>modules</code>	A named list of character strings specifying the names of modules to be loaded for the simulation. Note: the module name should correspond to the R source file from which the module is loaded. Example: a module named "caribou" will be sourced from the file 'caribou.R', located at the specified <code>modulePath(simList)</code> (see below).

objects	(optional) A vector of object names (naming objects that are in the calling environment of the <code>simInit</code> , which is often the <code>.GlobalEnv</code> unless used programmatically). NOTE: this mechanism will fail if object name is in a package dependency), or a named list of data objects to be passed into the <code>simList</code> (more reliable). These objects will be accessible from the <code>simList</code> as a normal list, e.g., <code>mySim\$obj</code> .
paths	An optional named list with up to 4 named elements, <code>modulePath</code> , <code>inputPath</code> , <code>outputPath</code> , and <code>cachePath</code> . See details. NOTE: Experimental feature now allows for multiple <code>modulePaths</code> to be specified in a character vector. The modules will be searched for sequentially in the first <code>modulePath</code> , then if it doesn't find it, in the second etc.
inputs	A <code>data.frame</code> . Can specify from 1 to 6 columns with following column names: <code>objectName</code> (character, required), <code>file</code> (character), <code>fun</code> (character), <code>package</code> (character), <code>interval</code> (numeric), <code>loadTime</code> (numeric). See <code>inputs()</code> and vignette("ii-modules") section about inputs.
outputs	A <code>data.frame</code> . Can specify from 1 to 5 columns with following column names: <code>objectName</code> (character, required), <code>file</code> (character), <code>fun</code> (character), <code>package</code> (character), <code>saveTime</code> (numeric) and <code>eventPriority</code> (numeric). If <code>eventPriority</code> is not set, it defaults to <code>.last()</code> . If <code>eventPriority</code> is set to a low value, e.g., 0, 1, 2 and <code>saveTime</code> is <code>start(sim)</code> , it should give "initial conditions". See <code>outputs()</code> and vignette("ii-modules") section about outputs.
loadOrder	An optional character vector of module names specifying the order in which to load the modules. If not specified, the module load order will be determined automatically.
notOlderThan	A time, as in from <code>Sys.time()</code> . This is passed into the <code>Cache</code> function that wraps <code>.inputObjects</code> . If the module uses the <code>.useCache</code> parameter and it is set to <code>TRUE</code> or <code>".inputObjects"</code> , then the <code>.inputObjects</code> will be cached. Setting <code>notOlderThan = Sys.time()</code> will cause the cached versions of <code>.inputObjects</code> to be refreshed, i.e., rerun.
debug	Optional tools for invoking debugging. Supplying a list will invoke the more powerful logging package. See details. Default is to use the value in <code>getOption("spades.debug")</code> .
progress	Logical (<code>TRUE</code> or <code>FALSE</code> show a graphical progress bar), character ("graphical", "text") or numeric indicating the number of update intervals to show in a graphical progress bar.
cache	Logical. If <code>TRUE</code> , then the <code>spades</code> call will be cached. This means that if the call is made again with the same <code>simList</code> , then <code>spades</code> will return the return value from the previous run of that exact same <code>simList</code> . Default <code>FALSE</code> . See Details. See also the vignette on caching for examples.
.plots	Character. Sets the parameter of this name in all modules. See <code>Plots()</code> for possible values. The parameter is intended to slowly take over from <code>.plotInitialTime</code> as a mechanism to turn on or off plotting. For backwards compatibility, if <code>.plotInitialTime</code> is not set in this <code>spades</code> call, but this <code>.plots</code> is used, two things will happen: setting this without "screen" will turn off all plotting; setting this with "screen" will trigger plotting for any modules that use this parameter but will have no effect on other modules. To get plotting, therefore, it may be necessary to also set <code>.plotInitialTime = start(sim)</code> .

<code>.plotInitialTime</code>	Numeric. Temporarily override the <code>.plotInitialTime</code> parameter for all modules. See Details.
<code>.saveInitialTime</code>	Numeric. Temporarily override the <code>.plotInitialTime</code> parameter for all modules. See Details.
<code>events</code>	A character vector or a named list of character vectors. If specified, the simulations will only do the events indicated here. If a named list, the names must correspond to the modules and the character vectors can be specific events within each of the named modules. With the list form, all unspecified modules will run <i>all</i> their events, including internal spades modules, e.g., <code>save</code> , that get invoked with the <code>outputs</code> argument in <code>simInit</code> . See example.
<code>...</code>	Arguments passed to <code>simInit()</code> and <code>spades()</code>

Value

Same as `spades()` (a `simList`) or

See Also

`simInit()`, `spades()`

simList-class

The simList class

Description

Contains the minimum components of a SpaDES simulation. Various slot accessor methods (i.e., get and set functions) are provided (see 'Accessor Methods' below).

Details

Based on code from chapter 7.8.3 of Matloff (2011): "Discrete event simulation". Here, we implement a discrete event simulation in a more modular fashion so it's easier to add simulation components (i.e., "simulation modules"). We use S4 classes and methods, and use `data.table()` instead of `data.frame()` to implement the event queue (because it is much more efficient).

Slots

`modules` List of character names specifying which modules to load.

`params` Named list of potentially other lists specifying simulation parameters.

`events` The list of scheduled events (i.e., event queue), which can be converted to a sorted `data.table` with `events(sim)`. See 'Event Lists' for more information.

`current` The current event, as a `data.table`. See 'Event Lists' for more information..

- completed** An environment consisting of completed events, with each object named a character representation of the order of events. This was converted from a previous version which was a list. This was changed because the list became slow as number of events increased. See 'Event Lists' for more information. It is kept as an environment of individual events for speed. The `completed` method converts it to a sorted `data.table`.
- depends** A `.simDeps` list of `.moduleDeps()` objects containing module object dependency information.
- simtimes** List of numerical values describing the simulation start and end times; as well as the current simulation time.
- inputs** a `data.frame` or `data.table` of files and metadata
- outputs** a `data.frame` or `data.table` of files and metadata
- paths** Named list of paths. See `?paths`. Partial matching is performed.
- .xData** Environment referencing the objects used in the simulation. Several "shortcuts" to accessing objects referenced by this environment are provided, and can be used on the `simList` object directly instead of specifying the `.xData` slot: `$`, `[[`, `ls`, `ls.str`, `objs`. See examples.
- .envir** Deprecated. Please do not use any more.

Accessor Methods

Several slot (and sub-slot) accessor methods are provided for use, and categorized into separate help pages:

<code>simList-accessors-envir()</code>	Simulation environment.
<code>simList-accessors-events()</code>	Scheduled and completed events.
<code>simList-accessors-inout()</code>	Passing data in to / out of simulations.
<code>simList-accessors-modules()</code>	Modules loaded and used; module dependencies.
<code>simList-accessors-objects()</code>	Accessing objects used in the simulation.
<code>simList-accessors-params()</code>	Global and module-specific parameters.
<code>simList-accessors-paths()</code>	File paths for modules, inputs, and outputs.
<code>simList-accessors-times()</code>	Simulation times.

Event Lists

The main event list is a sorted `data.table` (keyed) on `eventTime`, and `eventPriority`. The completed event list is an ordered list in the exact order that the events were executed. Each event is represented by a `data.table()` row consisting of:

<code>eventTime</code>	The time the event is to occur.
<code>moduleName</code>	The module from which the event is taken.
<code>eventType</code>	A character string for the programmer-defined event type.
<code>eventPriority</code>	The priority given to the event.

Note

The `simList` class extends the environment, by adding several slots that provide information about the metadata for a discrete event simulation. The environment slot, if accessed directly is `.xData` and this is where input and output objects from modules are placed. The `simList_()` class is similar, but it extends the `list` class. All other slots are the same. Thus, `simList` is identical to `simList_`, except that the former uses an environment for objects and the latter uses a list. The class `simList_` is only used internally when saving/loading, because saving/loading a list behaves more reliably than saving/loading an environment.

spades

Run a spatial discrete event simulation

Description

Here, we implement a simulation in a more modular fashion so it's easier to add submodules to the simulation. We use S4 classes and methods, and use `data.table` instead of `data.frame` to implement the event queue (because it is much faster).

Usage

```
spades(
  sim,
  debug = getOption("spades.debug"),
  progress = NA,
  cache,
  .plotInitialTime = NULL,
  .saveInitialTime = NULL,
  notOlderThan = NULL,
  events = NULL,
  .plots = getOption("spades.plots", NULL),
  ...
)

  debug = getOption("spades.debug"),
  progress = NA,
  cache,
  .plotInitialTime = NULL,
  .saveInitialTime = NULL,
  notOlderThan = NULL,
  events = NULL,
  .plots = getOption("spades.plots", NULL),
  ...
)

```

Arguments

<code>sim</code>	A <code>simList</code> simulation object, generally produced by <code>simInit</code> .
<code>debug</code>	Optional tools for invoking debugging. Supplying a list will invoke the more powerful logging package. See details. Default is to use the value in <code>getOption("spades.debug")</code> .
<code>progress</code>	Logical (TRUE or FALSE show a graphical progress bar), character ("graphical", "text") or numeric indicating the number of update intervals to show in a graphical progress bar.
<code>cache</code>	Logical. If TRUE, then the <code>spades</code> call will be cached. This means that if the call is made again with the same <code>simList</code> , then <code>spades</code> will return the return value from the previous run of that exact same <code>simList</code> . Default FALSE. See Details. See also the vignette on caching for examples.
<code>.plotInitialTime</code>	Numeric. Temporarily override the <code>.plotInitialTime</code> parameter for all modules. See Details.
<code>.saveInitialTime</code>	Numeric. Temporarily override the <code>.plotInitialTime</code> parameter for all modules. See Details.
<code>notOlderThan</code>	Date or time. Passed to <code>reproducible::Cache</code> to update the cache. Default is NULL, meaning don't update the cache. If <code>Sys.time()</code> is provided, then it will force a recache, i.e., remove old value and replace with new value. Ignored if cache is FALSE.
<code>events</code>	A character vector or a named list of character vectors. If specified, the simulations will only do the events indicated here. If a named list, the names must

	correspond to the modules and the character vectors can be specific events within each of the named modules. With the <code>list</code> form, all unspecified modules will run <i>all</i> their events, including internal spades modules, e.g., <code>save</code> , that get invoked with the <code>outputs</code> argument in <code>simInit</code> . See example.
<code>.plots</code>	Character. Sets the parameter of this name in all modules. See <code>Plots()</code> for possible values. The parameter is intended to slowly take over from <code>.plotInitialTime</code> as a mechanism to turn on or off plotting. For backwards compatibility, if <code>.plotInitialTime</code> is not set in this spades call, but this <code>.plots</code> is used, two things will happen: setting this without "screen" will turn off all plotting; setting this with "screen" will trigger plotting for any modules that use this parameter but will have no effect on other modules. To get plotting, therefore, it may be necessary to also set <code>.plotInitialTime = start(sim)</code> .
<code>...</code>	Any. Can be used to make a unique cache identity, such as "replicate = 1". This will be included in the Cache call, so will be unique and thus spades will not use a cached copy as long as anything passed in <code>...</code> is unique, i.e., not cached previously.

Details

This is the workhorse function in the SpaDES package. It runs simulations by implementing the rules outlined in the `simList`.

This function gives simple access to two sets of module parameters: `.plotInitialTime` and with `.plotInitialTime`. The primary use of these arguments is to temporarily turn off plotting and saving. "Temporary" means that the `simList` is not changed, so it can be used again with the `simList` values reinstated. To turn off plotting and saving, use `.plotInitialTime = NA` or `.saveInitialTime = NA`. NOTE: if a module did not use `.plotInitialTime` or `.saveInitialTime`, then these arguments will not do anything.

Value

Invisibly returns the modified `simList` object.

Caching with SpaDES

There are numerous ways in which Caching can be used within SpaDES. Please see the vignette <https://spades-core.predictiveecology.org/articles/iii-cache.html> for many examples. Briefly, functions, events, modules, entire spades calls or experiment calls (see <https://github.com/PredictiveEcology/SpaDES.experiment>) can be cached and mixtures of all of these will work. For functions, simply wrap the call with `Cache`, moving the original function name into the first argument of `Cache`. For events or modules, set the module parameters, `.useCache`, e.g., `simInit(..., parameters = list(myModule = list(.useCache = "init")))`. This can be set to an event name, which will cache that event, or a logical, which will cache *every* event in that module. Event and module caching makes most sense when the event or module only runs once, such as an initialization or data preparation event/module. Caching an entire simulation is actually just a function call to `simInitAndSpades`, for example. So, simply writing `Cache(simInitAndSpades, modules = ...)` will effectively cache a whole simulation. Finally for experiments, it is just like a function call: `Cache(simInitandExperiment, ...)`. The final way Caching can be done is in `experiment` or `spades`, by setting the `cache` argument.

If `cache` is `TRUE`, this allows for a seamless way to "save" results of a simulation. The user does not have to intentionally do any saving manually. Instead, upon a call to `spades` in which the `simList` is identical, the function will simply return the result that would have come if it had been rerun. Use this with caution, as it will return exactly the result from a previous run, even if there is stochasticity internally. Caching is only based on the input `simList`. See also the vignette on caching for examples.

debug

The most powerful way to use `debug` is to invoke the logging R package. To invoke this, `debug` must be a list with up to 3 named elements: `console`, `file`, and `debug`. Each of these list elements must be a list (including empty `list()` for defaults) with the sub-list elements here:

<code>console</code>	<code>level</code>	The level, see below, of information shown
<code>file</code>	<code>append</code>	Logical. If <code>TRUE</code> , the default, then log entries are appended to file, if it exists
	<code>file</code>	A filename. Defaults to <code>log.txt</code>
	<code>level</code>	The level, see below, of information shown
<code>debug</code>	See possible values below	

`level` can be a number from 0 to 100 or a character string matching one of the values in `logging::loglevels`. These are hierarchical levels of information passed to the console. Set a lower number for more information and a higher number for less information. Errors in code will be shown if `level` is set to "ERROR" or 40 or above; warnings in code will be shown if `level` is set to "WARN" or 30 or above; normal messages in code will be shown if `level` is set to "INFO" or 20 or above. For consistency with base R messaging, if default level is used, then normal messaging via `message` will be shown; this means that `suppressMessages` will work to suppress messaging only when `level` is set to "INFO" or 20. Some functions in the SpaDES ecosystem may have information at the lower levels, but currently, there are few to none.

`debug` is specified as a non-list argument to `spades` or as `list(debug = ...)`, then it can be a logical, a quoted call, a character vector or a numeric scalar (currently 1 or 2) or a list of any of these to get multiple outputs. This will be run at the start of every event. The following options for `debug` are available. Each of these can also be in a list to get multiple outputs:

<code>TRUE</code>	<code>current(sim)</code> will be printed at the start of each event
a function name (as character string)	If a function, then it will be run on the <code>simList</code> , e.g., "
<code>moduleName</code> (as character string)	All calls to that module will be entered interactively
<code>eventName</code> (as character string)	All calls that have that event name (in any module) will
<code>c(<moduleName>, <eventName>)</code>	Only the event in that specified module will be entered
Any other R expression expressed as a character string or quoted call	Will be evaluated with access to the <code>simList</code> as <code>sim</code> . I
A numeric scalar, currently 1 or 2 (maybe others)	This will print out alternative forms of event informati

If not specified in the function call, the package option `spades.debug` is used.

If `options("spades.browserOnError" = TRUE)` (experimental still) if there is an error, it will attempt to open a browser in the event where the error occurred. You can edit, and then press `c` to continue or `Q` to quit, plus all other normal interactive browser tools. `c` will trigger a reparse and events will continue as scheduled, starting with the one just edited. There may be some unexpected consequences if the `simList` objects had already been changed before the error occurred.

Note

The debug option is primarily intended to facilitate building simulation models by the user. Will print additional outputs informing the user of updates to the values of various simList slot components. See <https://github.com/PredictiveEcology/SpaDES/wiki/Debugging> for details.

`simInit()`

spadesOptions	<code>SpaDES.core</code> options
---------------	----------------------------------

Description

These provide top-level, powerful settings for a comprehensive SpaDES workflow. To see defaults, run `spadesOptions()`. See Details below.

Usage

`spadesOptions()`

Details

Below are options that can be set with `options("spades.xxx" = newValue)`, where `xxx` is one of the values below, and `newValue` is a new value to give the option. Sometimes these options can be placed in the user's `.Rprofile` file so they persist between sessions.

The following options are likely of interest to most users

OPTION

`spades.allowInitDuringSimInit`

`spades.browserOnError`

`reproducible.cachePath`

`spades.debug`

`spades.dotInputObjects`

`spades.DTthreads`

`spades.futureEvents`

`spades.logPath`

`spades.inputPath`

`spades.loadReqdPkgs`

Default is TRUE meaning that any reqdPkgs will be loaded via `Require` or `require`. I

`spades.lowMemory`

`spades.memoryUseInterval`

`spades.messagingNumCharsModule`

`spades.moduleCodeChecks`

`list(suppressParamUnused = FALSE, s`

`spades.moduleDocument`

`spades.modulePath`

`spades.moduleRepo`

`spades.nCompleted`

`spades.outputPath`

`spades.plots`

The value of this will be passed to `.plots` within

`spades.recoveryMode`

`spades.saveFileExtensions`

`spades.scratchPath`

`spades.sessionInfo`

`spades.switchPkgNamespaces`

`spades.testMemoryLeaks`

`spades.tolerance`

`spades.useragent`

`spades.useRequire`

Value

named list of the *default* package options.

Description

When loading objects into a `simList`, especially during the `simInit` call, and inside the `.inputObjects` functions of modules, it is often useful to know if an object in question will or has been by the user via the `inputs` or `objects` arguments, or by another module's `.inputObjects` while preparing its expected inputs (via `expectsInputs` in metadata), or if it will be supplied by another module during its "init" event. In all these cases, it may not be necessary for a given module to load any default value for its `expectsInputs`. This function can be used as a check to determine whether the module needs to proceed in getting and assigning its default value.

Usage

```
suppliedElsewhere(
  object,
  sim,
  where = c("sim", "user", "initEvent"),
  returnWhere = FALSE
)
```

Arguments

<code>object</code>	Character vector
<code>sim</code>	A <code>simList</code> in which to evaluate whether the object is supplied elsewhere
<code>where</code>	Character vector with one to three of "sim", "user", or "initEvent". Default is all three. Partial matching is used. See details.
<code>returnWhere</code>	Logical, default FALSE, whether the vector of length 3 logical should be returned, or a logical of length one

Details

`where` indicates which of three places to search, either "sim" i.e., the `simList`, which would be equivalent to `is.null(sim$objName)`, or "user" which would be supplied by the user in the `simInit` function call via `outputs` or `inputs` (equivalent to `!('defaultColor' %in% sim$.userSuppliedObjNames)`) or "initEvent", which would test whether a module that gets loaded **before** the present one **will** create it as part of its `outputs` (i.e., as indicated by `createsOutputs` in that module's metadata). There is a caveat to this test, however; if that other event also has the object as an `expectsInput`, then it would fail this test, as it *also* needs it as an input. This final one ("initEvent") does not explicitly test that the object will be created in the "init" event, only that it is in the `outputs` of that module, and that it is a module that is loaded prior to this one.

Value

logical

Examples

```
mySim <- simInit()
suppliedElsewhere("test", mySim) # FALSE
```

```

# supplied in the simList
mySim$test <- 1
suppliedElsewhere("test", mySim) # TRUE
test <- 1

# supplied from user at simInit time -- note, this object would eventually get into the simList
# but the user supplied values come *after* the module's .inputObjects, so
# a basic is.null(sim$test) would return TRUE even though the user supplied test
mySim <- simInit(objects = list("test" = test))
suppliedElsewhere("test", mySim) # TRUE

# Example with prepInputs
# Put chunks like this in your .inputObjects
if (!suppliedElsewhere("test", mySim))
  sim$test <- Cache(prepInputs, "raster.tif", "downloadedArchive.zip",
                    destinationPath = dataPath(sim), studyArea = sim$studyArea,
                    rasterToMatch = sim$otherRasterTemplate, overwrite = TRUE)

```

times

Time usage in SpaDES

Description

Functions for the `simtimes` slot of a `simList` object and its elements. To maintain modularity, the behaviour of these functions depends on where they are used. In other words, different modules can have their own `timeunit`. SpaDES converts these to seconds when running a simulation, but shows the user time in the units of the model as shown with `timeunit(sim)`

Usage

```

times(x, ...)

## S4 method for signature 'simList'
times(x)

times(x) <- value

## S4 replacement method for signature 'simList'
times(x) <- value

## S3 method for class 'simList'
time(x, unit, ...)

time(x) <- value

## S4 replacement method for signature 'simList'

```

```
time(x) <- value

end(x, ...)

## S3 method for class 'simList'
end(x, unit, ...)

end(x) <- value

## S4 replacement method for signature 'simList'
end(x) <- value

start(x, ...)

## S3 method for class 'simList'
start(x, unit = NULL, ...)

start(x) <- value

## S4 replacement method for signature 'simList'
start(x) <- value

timeunit(x)

## S4 method for signature 'simList'
timeunit(x)

timeunit(x) <- value

## S4 replacement method for signature 'simList'
timeunit(x) <- value

timeunits(x)

## S4 method for signature 'simList'
timeunits(x)

elapsedTime(x, ...)

## S3 method for class 'simList'
elapsedTime(x, byEvent = TRUE, units = "auto", ...)
```

Arguments

x	A simList
...	Additional parameters.
value	A time, given as a numeric, optionally with a unit attribute, but this will be deduced from the model time units or module time units (if used within a module).

<code>unit</code>	Character. One of the time units used in SpaDES.
<code>byEvent</code>	Logical. If TRUE, the elapsed time will be by module and event; FALSE will report only by module. Default is TRUE.
<code>units</code>	character string. Units in which the results are desired. Can be abbreviated.

Details

`timeunit` will extract the current units of the time used in a simulation (i.e., within a `spades` call). If it is set within a `simInit`, e.g., `times=list(start=0, end=52, timeunit = "week")`, it will set the units for that simulation. By default, a `simInit` call will use the smallest unit contained within the metadata for the modules being used. If there are parent modules, then the parent module `timeunit` will be used even if one of its children is a smaller `timeunit`. If all modules, including parents, are set to NA, `timeunit` defaults to seconds. If parents are set to NA, then the set of modules defined by that parent module will be given the smallest units of the children.

Currently, available units are "second", "hours", "day", "week", "month", and "year" can be used in the metadata of a module.

The user can also define a new unit. The unit name can be anything, but the function definition must be of the form `dunitName`, e.g., `dyear` or `dfortnight`. The unit name is the part without the `d` and the function name definition includes the `d`. This new function, e.g., `dfortnight <- function(x) lubridate::duration(dday(14))` can be placed anywhere in the search path or in a module.

`timeunits` will extract the current units of the time of all modules used in a simulation. This is different from `timeunit` because it is not necessarily associated with a `spades` call.

In many cases, the "simpler" use of each of these functions may be slower computationally. For instance, it is much faster to use `time(sim, "year")` than `time(sim)`. So as a module developer, it is advantageous to write out the longer one, minimizing the looking up that R must do.

Value

Returns or sets the value of the slot from the `simList` object.

Note

These have default behaviour that is based on the calling frame `timeunit`. When used inside a module, then the time is in the units of the module. If used in an interactive mode, then the time will be in the units of the simulation.

Additional methods are provided to access the current, start, and end times of the simulation:

<code>time</code>	Current simulation time.
<code>start</code>	Simulation start time.
<code>end</code>	Simulation end time.
<code>timeunit</code>	Simulation <code>timeunit</code> .
<code>timeunits</code>	Module <code>timeunits</code> .
<code>times</code>	List of all simulation times (current, start, end, <code>timeunit</code>).

Examples

```
# Elapsed Time
s1 <- simInit()
s2 <- spades(s1)
elapsedTime(s2)
elapsedTime(s2, units = "mins")
```

updateList	<i>Update elements of a named list with elements of a second named list</i>
------------	---

Description

Defunct. Use [utils::modifyList\(\)](#) (which can not handle NULL) or [Require::modifyList2\(\)](#) for case with >2 lists and can handle NULL lists.

Usage

```
updateList(x, y)
```

Arguments

x, y	a named list
------	--------------

Value

A named list, with elements sorted by name. The values of matching elements in list y replace the values in list x.

Author(s)

Alex Chubaty

use_gha	<i>Use GitHub actions for automated module checking</i>
---------	---

Description

See corresponding vignette for more information.

Usage

```
use_gha(name, path)
```

Arguments

name	module name
path	module path

Value

Invoked for its side effect of creating new GitHub Actions workflow files.

writeEventInfo	<i>Write simulation event info to file</i>
----------------	--

Description

Useful for debugging.

Usage

```
writeEventInfo(sim, file = "events.txt", append = FALSE)
```

Arguments

sim	A simList object.
file	Character specifying the file name (default "events.txt").
append	Logical indicating whether to append to the file (default FALSE).

Value

Nothing returned. Invoked for its side effect of writing to file.

Author(s)

Alex Chubaty

writeRNGInfo	<i>Write RNG state info to file</i>
--------------	-------------------------------------

Description

Useful for debugging and ensuring reproducibility.

Usage

```
writeRNGInfo(file = "seed.txt", append = FALSE)
```

Arguments

file	Character specifying the filename (default "seed.txt").
append	Logical indicating whether to append to the file (default FALSE).

Value

Nothing returned. Invoked for its side effect of writing to file.

Author(s)

Alex Chubaty

zipModule	<i>Create a zip archive of a module subdirectory</i>
-----------	--

Description

The most common use of this would be from a "modules" directory, rather than inside a given module.

Usage

```
zipModule(name, path, version, data = FALSE, ...)

## S4 method for signature 'character,character,character'
zipModule(name, path, version, data = FALSE, ...)

## S4 method for signature 'character,missing,character'
zipModule(name, path, version, data = FALSE, ...)

## S4 method for signature 'character,missing,missing'
zipModule(name, path, version, data = FALSE, ...)

## S4 method for signature 'character,character,missing'
zipModule(name, path, version, data = FALSE, ...)
```

Arguments

name	Character string giving the module name.
path	A file path to a directory containing the module subdirectory.
version	The module version.
data	Logical. If TRUE, then the data subdirectory will be included in the zip. Default is FALSE.
...	Additional arguments to <code>zip()</code> : e.g., add "-q" using <code>flags="-q -r9X"</code> (the default flags are "-r9X").

Value

NULL (invisibly). Invoked for its side effect of zipping module files.

Author(s)

Eliot McIntire and Alex Chubaty

zipSimList	<i>Zip a simList and various files</i>
------------	--

Description

zipSimList will save the simList and file-backed Raster* objects, plus, optionally, files identified in outputs(sim) and inputs(sim). This uses Copy under the hood, to not affect the original simList.

These functions have been moved to other packages.

Usage

```
zipSimList(sim, zipfile, ..., outputs = TRUE, inputs = TRUE, cache = FALSE)

experiment(...)

experiment2(...)

POM(...)

simInitAndExperiment(...)

loadPackages(...)
```

Arguments

sim	Either a simList or a character string of the name of a simList that can be found in envir. Using a character string will assign that object name to the saved simList, so when it is recovered it will be given that name.
zipfile	A character string indicating the filename for the zip file. Passed to zip.
...	Unused.
outputs	Logical. If TRUE, all files identified in outputs(sim) will be included in the zip.
inputs	Logical. If TRUE, all files identified in inputs(sim) will be included in the zip.
cache	Logical. Not yet implemented. If TRUE, all files in cachePath(sim) will be included in the archive. Defaults to FALSE as this could be large, and may include many out of date elements. See Details.

[,simList,character,ANY-method

Extract an intact simList but with subset of objects

Description

This is copies the non-object components of a simList (e.g., events, etc.) then selects only the objects listed in i using Copy(mget(i, envir(sim))) and adds them to the returned simList.

Usage

```
## S4 method for signature 'simList,character,ANY'
x[i, j, ..., drop = TRUE]
```

Arguments

x	A simList
i	A character vector of objects to select.
j	Not used.
...	Not used.
drop	Not used.

Value

The [, method returns a complete simList class with all the slots copied from the original, but only the named objects in i are returned.

Author(s)

Eliot McIntire

Examples

```
s <- simInit()
s$a <- 1
s$b <- 2
s$d <- 3
s[c("a", "d")] # a simList with only 2 objects
```
