ctqr-package

Censored and Truncated Quantile Regression

Description

Fit quantile regression models to survival data, allowing for right censoring, left truncation, and interval censoring.

Details

Package: ctqr Type: Package Version: 2.2

Date: 2025-07-23 License: GPL-2

The main function ctqr is used for model fitting. Other documented functions are predict.ctqr, to obtain prediction from a ctqr object, plot.ctqr, to plot quantile regression coefficients, and ctqr.control, that can be used to set the operational parameters for the estimation algorithm.

pchreg, that is used to compute a preliminary estimate of the conditional outcome distribution.

ctqr 3

ctqr	Censored and Truncated Quantile Regression

Description

Fits a quantile regression model to possibly censored and truncated data, e.g., survival data.

Usage

```
ctqr(formula, data, weights, p = 0.5, CDF, control = ctqr.control(), ...)
```

Arguments

formula	an object of class "formula": a symbolic description of the regression model. The response must be a Surv object as returned by Surv (see 'Details').
data	an optional data frame containing the variables in the model.
weights	an optional vector of weights to be used in the fitting process. The weights will always be normalized to sum to the sample size. This implies that, for example, using double weights will not halve the standard errors.
р	numerical vector indicating the order of the quantile(s) to be fitted.
CDF	an object of class "pch", i.e., the result of a call to pchreg. If missing, it will be computed internally with default settings. See 'Details'.
control	a list of operational parameters for the optimization algorithm, usually passed via ctqr.control.
	for future arguments.

Details

This function implements the method described in Frumento and Bottai (2017) for censored, truncated quantile regression, and Frumento (2022) for interval-censored quantile regression.

The left side of formula must be of the form Surv(time, event) if the data are right-censored, Surv(time0, time, event) if the data are right-censored and left-truncated (time0 < time, time0 can be -Inf), and Surv(time1, time2, type = "interval2") if the data are interval-censored (use time1 = time2 for exact observations, time1 = -Inf or NA for left-censored, and time2 = Inf or NA for right-censored). Using Surv(time) is also allowed and indicates that the data are neither censored nor truncated.

The conditional distribution function (CDF) of the response variable represents a nuisance parameter and is estimated preliminarly via pchreg. If missing, CDF = pchreg(formula) is used as default. See the "Note" and the documentation of pchreg.

Estimation is carried out using an algorithm for gradient-based optimization. To estimate the asymptotic covariance matrix, standard two-step procedures are used (e.g., Ackerberg et al., 2012).

4 ctqr

Value

An object of class "ctqr", which is a list with the following items:

p the quantile(s) being estimated.

coefficients a named vector or matrix of quantile regression coefficients.

call the matched call.

n.it the number of iterations.

converged logical. The convergence status.

fitted the fitted values.

terms the terms object used.

mf the model frame used.

covar the estimated asymptotic covariance matrix.

CDF the used CDF.

Note that the dimension of all items, except call, terms, mf, and CDF, is the same as the dimension of p. For example, if p = c(0.25, 0.5, 0.75), coefficients and fitted will be 3-columns matrices; n.it and converged will be vectors of 3 elements; and covar will be a list of three covariance matrices.

The generic accessor functions summary, plot, predict, coef, terms, nobs, can be used to extract information from the model. The functions waldtest (from the package **lmtest**), and linearHypothesis (from the package **car**) can be used to perform Wald test, and to test linear restrictions. These functions, however, will only work if p is scalar.

Note

NOTE 1. The first-step estimator (the CDF argument) is computed using the pchreg function of the **pch** package. To be correctly embedded in ctqr, a pch object must be constructed using the same observations, in the same order.

If the first-step estimator is biased, and there is censoring or truncation, the estimates of the quantile regression coefficients and their standard errors will also be biased.

If the data are neither censored nor truncated, the CDF does not enter the estimating equation of the model. However, since the first-step estimator is used to compute the starting points, the final estimates may be sensitive to the supplied CDF.

NOTE 2. Right-censoring is a special case of interval censoring, in which exact events are identified by time2 = time1, while censored observations have time2 = Inf. Note, however, that ctqr(Surv(time1, time2, type = "interval2") \sim x) will not be identical to ctqr(Surv(time = time1, event = (time2 < Inf)) \sim x). The estimating equation used for interval-censored data is that described in Frumento (2022), while that used for right-censored data is that of Frumento and Bottai (2017). The two estimating equations are only asymptotically equivalent.

```

ctqr.control

Auxiliary Function for Root Search

Description

This functions can be used within a call to ctqr, to control the operational parameters of the root search algorithm.

Usage

```
ctqr.control(tol = 1e-06, maxit = 1000, a = 0.5, b = 1.25)
```

Arguments

tol	positive convergence tolerance: the algorithm stops when the maximum absolute change between two consecutive estimates is smaller than tol.
maxit	maximum number of iterations.
a, b	numeric scalar with $0 < a < 1$ and $b > 1$. See 'Details'.

Details

For a current estimate beta, a new estimate is computed as beta_new = beta + delta*s(beta), where s(beta) is the current value of the estimating equation and delta is a positive multiplier. If sum(s(beta_new)^2) < sum(s(beta)^2), the iteration is accepted and delta is multiplied by b. Otherwise, beta_new is rejected and delta is multiplied by a. By default, a = 0.5 and b = 1.25. Choosing a,b closer to 1 may result in a more accurate estimate, but will require a larger number of iterations.

plot.ctqr 7

Value

The function returns its arguments. If some was not correctly specified, it is set to its default and a warning message is returned.

ctqr

plot.ctqr

Plot Quantile Regression Coefficients

Description

Plots quantile regression coefficients $\beta(p)$ as a function of p, based on a fitted model of class "ctqr".

Usage

```
## S3 method for class 'ctqr'
plot(x, which = NULL, ask = TRUE, ...)
```

Arguments

X	an object of class "ctqr".
which	an optional numerical vector indicating which coefficient(s) to plot. If which = NULL, all coefficients are plotted.
ask	logical. If which = NULL and ask = TRUE (the default), you will be asked interactively which coefficients to plot.
	additional graphical parameters, that can include xlim, ylim, xlab, ylab, col, lwd. See par.

Details

With this command, a plot of $\beta(p)$ versus p is created, provided that at least two quantiles have been estimated. Dashed lines represent 95% confidence intervals, while the horizontal dotted line indicates the zero.

8 predict.ctqr

Examples

```
# using simulated data

n <- 1000
x <- runif(n)
t <- 1 + x + rexp(n)
c <- runif(n, 1,10)
y <- pmin(c,t)
d <- (t <= c)

par(mfrow = c(1,2))
plot(ctqr(Surv(y,d) ~ x, p = seq(0.05,0.95,0.05)), ask = FALSE)</pre>
```

predict.ctqr

Prediction After Quantile Regression

Description

This function returns predictions for an object of class "ctqr".

Usage

```
## S3 method for class 'ctqr'
predict(object, newdata, se.fit = FALSE, ...)
```

Arguments

object a ctqr object.

newdata optional data frame in which to look for variables with which to predict. It must include all the covariates that enter the quantile regression model. If omitted, the fitted values are used.

se.fit logical. If TRUE, standard errors of the predictions are also computed.

for future methods.

Details

This function produces predicted values obtained by evaluating the regression function at newdata (which defaults to model.frame(object)).

Value

If se = FALSE, a matrix of fitted values, with rows corresponding to different observations, and one column for each value of object\$p. If se = TRUE, a list with two items:

fit a matrix of fitted values, as described above. se.fit a matrix of estimated standard errors. predict.ctqr 9
