

# Package ‘ergm.rank’

July 22, 2025

**Version** 4.1.1

**Date** 2024-06-15

**Title** Fit, Simulate and Diagnose Exponential-Family Models for Rank-Order Relational Data

**Depends** R ( $\geq 4.0$ ), ergm ( $\geq 4.2.2$ ), network ( $\geq 1.15$ )

**Imports** statnet.common ( $\geq 4.2.0$ ), Rdpack ( $\geq 2.4$ ), utils

**LinkingTo** ergm

**Suggests** covr, knitr, rmarkdown

**RdMacros** Rdpack

**Description** A set of extensions for the 'ergm' package to fit weighted networks whose edge weights are ranks. See Krivitsky and Butts (2017) <[doi:10.1177/0081175017692623](https://doi.org/10.1177/0081175017692623)> and Krivitsky, Hunter, Morris, and Klumb (2023) <[doi:10.18637/jss.v105.i06](https://doi.org/10.18637/jss.v105.i06)>.

**License** GPL-3 + file LICENSE

**URL** <https://statnet.org>

**BugReports** <https://github.com/statnet/ergm.rank/issues>

**VignetteBuilder** rmarkdown, knitr

**RoxygenNote** 7.3.1

**Encoding** UTF-8

**NeedsCompilation** yes

**Author** Pavel N. Krivitsky [aut, cre] (ORCID: <<https://orcid.org/0000-0002-9101-3362>>),

ergm.rank-package	<i>Fit, Simulate and Diagnose Exponential-Family Models for Rank-Order Relational Data</i>
-------------------	--

---

## Description

[ergm.rank](#) is a set of extensions to package [ergm](#) to fit and simulate from exponential-family random graph models for networks whose edge weights are ranks. Mainly, it implements the [CompleteOrder](#) reference measure for valued ERGMs (Krivitsky 2012; Krivitsky et al. 2023) and provides some rank-order change statistics (`search.ergmTerms("ordinal")` for a list) (Krivitsky and Butts 2017).

## Details

When publishing results obtained using this package, please cite the original authors as described in `citation(package="ergm.rank")`.

All programs derived from this package must cite it.

This package contains functions specific to using [ergm](#) to model networks whose dyad values are ranks. Examples include preferences, valued ties reduced to ranks, etc.. These terms have a specialized interpretation, and are therefore generally prefixed by "rank.", though they should take any valued data.

For detailed information on how to download and install the software, go to the Statnet project website: <https://statnet.org>. A tutorial, support newsgroup, references and links to further resources are provided there.

## Author(s)

CompleteOrder-ergmReference

*A uniform distribution over the possible complete orderings of the alters by each ego*

---

## Description

A uniform distribution over the possible complete orderings of the alters by each ego

## Usage

```
# CompleteOrder
```

## See Also

[ergmReference](#) for index of reference distributions currently visible to the package.

**Keywords:** ordinal, valued

newcomb

*Newcomb's Fraternity Networks***Description**

These 14 networks record weekly sociometric preference rankings from 17 men attending the University of Michigan in the fall of 1956; Data were collected longitudinally over 15 weeks, although data from week 9 are missing.

**Format**

A list of 15 networks.

**Details**

The men were recruited to live in off-campus (fraternity) housing, rented for them as part of the Michigan Group Study Project supervised by Theodore Newcomb from 1953 to 1956. All were incoming transfer students with no prior acquaintance of one another.

The data set, derived from one in the unreleased netdata package, contains a network list newcomb with 14 networks. Each network is complete and contains two edge attributes:

**list("rank")** the preference of the  $i$ th man for the  $j$ th man from 1 through 16, with 1 being the highest preference.

**list("descrank")** the same, but 1 indicates lowest preference.

**Licenses and Citation**

If the source of the data set does not specified otherwise, this data set is protected by the Creative Commons License <https://creativecommons.org/licenses/by-nc-nd/2.5/>.

When publishing results obtained using this data set the original authors should be cited. In addition this should be cited as:

## Examples

```
# Note: This takes a long time.
data(newcomb)

# Fit a model for the transition between initial (time 0) ranking and
# ranking after one week (time 1). Note that MCMC interval has been
# decreased to save time.
newcomb.1.2.fit <- ergm(newcomb[[2]]~
  rank.inconsistency(newcomb[[1]], "descrank")+
  rank.deference+rank.nonconformity("all")+
  rank.nonconformity("localAND"),
  response="descrank", reference=~CompleteOrder,
  control=control.ergm(MCMC.interval=10))
# Check MCMC diagnostics (barely adequate).
mcmc.diagnostics(newcomb.1.2.fit)
summary(newcomb.1.2.fit)
```

---

rank.deference-ergmTerm

*Deference (aversion)*

---

## Description

Measures the amount of "deference" in the network: configurations where an ego  $i$  ranks an alter  $j$  over another alter  $k$ , but  $j$ , in turn, ranks  $k$  over  $i$ . A lower-than-chance value of this statistic and/or a negative coefficient implies a form of mutuality in the network.

## Usage

```
# valued: rank.deference
```

## See Also

**Keywords:** directed, ordinal, triad-related, valued

---

rank.edgescov-ergmTerm *Dyadic covariates*

---

### Description

Models the effect of a dyadic covariate on the propensity of an ego  $i$  to rank alter  $j$  highly.

### Usage

```
# valued: rank.edgescov(x, attrname)
```

### Arguments

`x, attrname` either a square matrix of covariates, one for each possible edge in the network, the name of a network attribute of covariates, or a network; if the latter, or if the network attribute named by `x` is itself a network, optional argument `attrname` provides the name of the quantitative edge attribute to use for covariate values (in this case, missing edges in `x` are assigned a covariate value of zero).

### See Also

[ergmTerm](#) for index of model terms currently visible to the package.

**Keywords:** directed, ordinal, quantitative dyadic attribute, valued

---

rank.inconsistency-ergmTerm  
*(Weighted) Inconsistency*

---

### Description

Measures the amount of disagreement between rankings of the focus network and a fixed covariate network `x`, by counting the number of pairwise comparisons for which the two networks disagree.

### Usage

```
# valued: rank.inconsistency(x, attrname, weights, wtname, wtcenter)
```

### Arguments

`x, attrname` `x` can be a [network](#) with an edge attribute `attrname` containing the ranks or a matrix of appropriate dimension containing the ranks. If `x` is not given, it defaults to the LHS network, and if `attrname` is not given, it defaults to the response edge attribute.

**weights** optional parameter to weigh the counts. Can be either a 3D  $n \times n \times n$  -array whose  $(i, j, k)$  th element gives the weight for the comparison by  $i$  of  $j$  and  $k$  or a function taking three arguments,  $i$ ,  $j$ , and  $k$ , and returning the weight of this comparison.

**wtname, wtcenter** If **wtcenter**=TRUE , the calculated weights will be centered around their mean. **wtname** can be used to label this term.

### See Also

[ergmTerm](#) for index of model terms currently visible to the package.

**Keywords:** directed, ordinal, quantitative triadic attribute, valued

---

rank.nodeicov-ergmTerm

*Attractiveness/Popularity covariates*

---

### Description

Models the effect of one or more nodal covariates on the propensity of an actor to be ranked highly by the others.

### Usage

```
# valued: rank.nodeicov(attr)
```

### Arguments

**attr** a vertex attribute specification (see Specifying Vertex attributes and Levels (?nodal\_attributes) for details.)

### See Also

[ergmTerm](#) for index of model terms currently visible to the package.

**Keywords:** directed, ordinal, quantitative nodal attribute, valued

---

rank.nonconformity-ergmTerm  
*Nonconformity*

---

### Description

Measures the amount of "nonconformity" in the network: configurations where an ego  $i$  ranks an alter  $j$  over another alter  $k$ , but ego  $l$  ranks  $k$  over  $j$ .

### Usage

# valued: rank.nonconformity(to, par)

### Arguments

to	<p>which controls to whom an ego may conform:</p> <ul style="list-style-type: none"> <li>• "all" (the default): Nonconformity to all egos is counted. A lower-than-chance value of this statistic and/or a negative coefficient implies a degree of consensus in the network.</li> <li>• "localAND": Nonconformity of <math>i</math> to ego <math>l</math> regarding the relative ranking of <math>j</math> and <math>k</math> is only counted if <math>i</math> ranks <math>l</math> over both <math>j</math> and <math>k</math>. A lower-than-chance value of this statistic and/or a negative coefficient implies a form of hierarchical transitivity in the network. This is the recommended form of local nonconformity (over "local1" and "local2").</li> <li>• "local1": Nonconformity of <math>i</math> to ego <math>l</math> regarding the relative ranking of <math>j</math> and <math>k</math> is only counted if <math>i</math> ranks <math>l</math> over <math>j</math>.</li> <li>• "local2": Nonconformity of <math>i</math> to ego <math>l</math> regarding the relative ranking of <math>j</math> and <math>k</math> is only counted if <math>i</math> ranks <math>l</math> over <math>k</math>.</li> <li>• "thresholds": Nonconformity of <math>i</math> to ego <math>l</math> regarding the relative ranking of <math>j</math> and <math>k</math> is only counted if <math>i</math> ranks <math>l</math> above par, where par can be a vector with multiple thresholds.</li> <li>• "geometric": Nonconformity of <math>i</math> to ego <math>l</math> regarding the relative ranking of <math>j</math> and <math>k</math> is weighted by par taken to the power of the rank of <math>l</math> by <math>i</math>, where par is a scalar.</li> </ul>
par	additional parameters for some types of nonconformity.
