Description

Methods for fitting log-link GLMs and GAMs to binomial data, including EM-type algorithms with more stable convergence properties than standard methods.

Details

Package: logbin
Type: Package
Version: 2.0.6
License: GPL (>= 2)

This package provides methods to fit generalised linear models (GLMs) and generalised additive models (GAMs) with log link functions to binomial data, which can be used to estimate adjusted relative risks. It has two primary functions: logbin and logbin.smooth, together with various supporting functions.

Standard GLM routines such as base R's glm typically use a modified Fisher scoring algorithm, but this can experience numerical problems and fail to converge to the maximum likelihood estimate (MLE). The glm2 package improves on this but can still have difficulties, particularly when the MLE is on or near the boundary of the parameter space (Marschner, 2015).

Alternative methods for finding the MLE are provided in this package. For both GLMs and GAMs, two approaches based on the EM algorithm can be used: a combinatorial EM (CEM) algorithm (Marschner, 2014) or an expanded EM algorithm. These accommodate the parameter constraints and are more stable than iteratively reweighted least squares.

In a CEM algorithm, a collection of restricted parameter spaces is defined which covers the full parameter space, and an EM algorithm is applied within each restricted parameter space in order to find a collection of restricted maxima of the log-likelihood function, from which can be obtained the global maximum over the full parameter space. The methodology implemented for this algorithm is presented in Marschner and Gillett (2012) and Donoghoe and Marschner (2015).

anova.logbin 3

In the expanded EM approach, additional parameters are added to the model, and an EM algorithm finds the MLE of this overparameterised model by imposing constraints on each individual parameter. This requires a single application of the EM algorithm.

In each case, the EM algorithm may be accelerated by using the capabilities of the **turboEM** package.

For GLMs, an adaptive barrier approach, which uses a constrained optimisation algorithm, is also provided.

anova.logbin

Analysis of Deviance for logbin Fits

Description

Compute an analysis of deviance table for more than one GLM fitted using logbin.

Usage

```
## S3 method for class 'logbin'
anova(object, ..., test = NULL)
```

4 B.Iso

Arguments

```
object, ... objects of class "logbin", typically the result of a call to logbin, or a list of objects for the "logbinlist" method.

test a character string, (partially) matching one of "Chisq", "LRT", "Rao", "F" or "Cp". See stat.anova.
```

Details

Unlike anova. glm, specifying a single object is not allowed.

The table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Models where the MLE lies on the boundary of the parameter space will be automatically removed from the list (with a warning), because asymptotic results may not apply to such models.

The table will optionally contain test statistics (and p-values) comparing the reduction in deviance for the row to the residuals. Mallows' C_p statistic is the residual deviance plus twice the estimate of σ^2 times the residual degrees of freedom, which is closely related to AIC. You can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).

Value

An object of class "anova" inheriting from class "data.frame".

B.Iso

Defining Smooths in logbin.smooth Formulae

Description

Function used in the definition of smooth terms within logbin. smooth model formulae. The function does not evaluate a smooth — it exists purely to help set up a model using smooths.

B.Iso 5

Usage

```
B(..., knots = NULL, knot.range = 0:5)
Iso(...)
```

Arguments

... variable that this smooth is a function of. Note that unlike gam, smooths that are

functions of more than one variable are not supported.

knots *unique* positions of *interior* knots of a B-spline basis. Boundary knots are cre-

ated automatically.

knot.range if knots is not specified, a vector containing a series of non-negative integers

denoting the number of interior knots for which the model will be fit. These are

placed at evenly-spaced quantiles of the observed covariate values.

At least one of knots or knot. range must be non-missing.

Details

The function does not evaluate the variable arguments; the output from this function is used when producing the model matrix, at which point the actual basis functions are constructed.

B is used to specify an order-3 B-spline basis (which can be restricted to be monotonically non-decreasing via the mono argument in logbin.smooth). If length(knot.range) > 1, models with each of the specified number of interior knots will be fit, and the model with the best (smallest) aic.c will be returned.

Iso is used to specify an isotonic basis, designed such that the resulting function has non-negative increments at each observed covariate value. When Iso is used, the resulting function will always be monotonically non-decreasing, regardless of the value of mono.

Value

An object of class "B. smooth" (for B) or "Iso. smooth" (for Iso), which is a list with the following elements:

term name of the term provided in the . . . argument.

termlabel label for the term in the model; e.g. for term "x" it will be "B(x)" or "Iso(x)".

knots vector of interior knots (if specified). NA for Iso.
knot.range vector of number of interior knots. NA for Iso.

confint.logbin

Confidence Intervals for logbin Model Parameters

Description

Computes confidence intervals for one or more parameters in a fitted logbin model.

Usage

```
## S3 method for class 'logbin'
confint(object, parm, level = 0.95, ...)
```

Arguments

object a fitted model object, resulting from a call to logbin.

parm a specification of which parameters are to be given confidence intervals, either

a vector of numbers or a vector of names. If missing, all parameters are consid-

ered.

level the confidence level required.

... additional argument(s) passed to confint.default.

Details

Calculates confidence intervals for model parameters assuming asymptotic normality and using the result from vcov.logbin(object). As such, if the MLE is on the boundary of the parameter space, (as per object\$boundary) the normality assumption is invalid and NA is returned.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1-(1-level)/2 in % (by default 2.5% and 97.5%).

logbin

Log-Binomial Regression

Description

logbin fits relative risk (log-link) binomial regression models.

Usage

```
logbin(formula, mono = NULL, data, subset, na.action, start = NULL,
    offset, control = list(...), model = TRUE,
    method = c("cem", "em", "glm", "glm2", "ab"),
    accelerate = c("em", "squarem", "pem", "qn"),
    control.method = list(), warn = TRUE, ...)
```

Arguments

formula an object of class "formula"	" (or one that can be coerced into that class): a
--------------------------------------	---

symbolic description of the model to be fitted. The details of model specification are given under "Details". Note that the model must contain an intercept, and 2nd-order terms (such as interactions) or above are currently not supported by

the "cem" and "em" methods — see "Note".

mono a vector indicating which terms in formula should be restricted to have a mono-

tonically non-decreasing relationship with the outcome. May be specified as

names or indices of the terms.

method = "glm" and "glm2" cannot impose monotonicity constraints, and they

are not currently supported for method = "ab".

data an optional data frame, list or environment (or object coercible by as.data.frame

to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment (formula), typically the environment

from which logbin is called.

subset an optional vector specifying a subset of observations to be used in the fitting

process.

na.action a function which indicates what should happen when the data contain NAs. The

default is set be the na.action setting of options, and is na.fail if that is unset. The 'factory-fresh' default is na.omit. Another possible value is NULL,

no action. Value na. exclude can be useful.

start starting values for the parameters in the linear predictor.

offset this can be used to specify an *a priori* known component to be included in the

linear predictor during fitting. This should be NULL or a *non-positive* numeric vector of length equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if more than one is specified

their sum is used. See model.offset.

control a list of parameters for controlling the fitting process, passed to logbin.control.

With method = "cem", epsilon should be smaller than bound.tol.

model a logical value indicating whether the *model frame* should be included as a com-

ponent of the returned value.

method a character string that determines which algorithm to use to find the MLE. The

main purpose of logbin is the implementation of stable EM-type algorithms: "cem" for the combinatorial EM algorithm, which cycles through a sequence of constrained parameter spaces, or "em" for a single EM algorithm based on an

overparameterised model.

"ab" implements an adaptive barrier method, using the constrOptim function.
"glm" or "glm2" may be used to compare the results from the usual IWLS

algorithms on the same model.

accelerate for the "cem" and "em" methods, a character string that determines the acceler-

ation algorithm to be used, (partially) matching one of "em" (no acceleration — the default), "squarem", "pem" or "qn". See turboem for further details. Note

that "decme" is not permitted.

control.method a list of control parameters for the fitting algorithm.

This is passed to the control.method argument of turboem if method = "cem"

or "em".

If method = "ab", this is passed to the control argument of constrOptim (and hence to optim — see this documentation for full details). Note that the trace and maxit elements are ignored and the equivalent items from the supplied logbin.control argument are used instead. May also contain element method (default "BFGS"), which is passed to the method argument of constrOptim.

If any items are not specified, the defaults are used.

warn a logical indicating whether or not warnings should be provided for non-convergence

or boundary values.

arguments to be used to form the default control argument if it is not supplied

directly.

Details

logbin fits a generalised linear model (GLM) with a binomial error distribution and log link function. Predictors are assumed to be continuous, unless they are of class factor, or are character or logical (in which case they are converted to factors). Specifying a predictor as monotonic using the mono argument means that for continuous terms, the associated coefficient will be restricted to be non-negative, and for categorical terms, the coefficients will be non-decreasing in the order of the factor levels. This allows semi-parametric monotonic regression functions, in the form of unsmoothed step-functions. For smooth regression functions see logbin. smooth.

As well as allowing monotonicity constraints, the function is useful when a standard GLM routine, such as glm, fails to converge with a log-link binomial model. For convenience in comparing convergence on the same model, logbin can be used as a wrapper function to glm and glm2 through the method argument.

If glm does achieve successful convergence, and logbin converges to an interior point, then the two results will be identical. However, as illustrated in one of the examples below, glm may still experience convergence problems even when logbin converges to an interior point. Note that if logbin converges to a boundary point, then it may differ slightly from glm even if glm successfully converges, because of differences in the definition of the parameter space. logbin produces valid

fitted values for covariate values within the Cartesian product of the observed range of covariate values, whereas glm produces valid fitted values just for the observed covariate combinations (assuming it successfully converges). This issue is only relevant when logbin converges to a boundary point. The adaptive barrier approach defines the parameter space in the same way as glm, so the same comments apply when comparing its results to those from method = "cem" or "em".

The main computational method is an EM-type algorithm which accommodates the parameter contraints in the model and is more stable than iteratively reweighted least squares. This is done in one of two ways, depending on the choice of the method argument.

method = "cem" implements a CEM algorithm (Marschner, 2014), in which a collection of restricted parameter spaces is defined that covers the full parameter space, and an EM algorithm is applied within each restricted parameter space in order to find a collection of restricted maxima of the log-likelihood function, from which can be obtained the global maximum over the full parameter space. See Marschner and Gillett (2012) for further details.

method = "em" implements a single EM algorithm on an overparameterised model, and the MLE of this model is transformed back to the original parameter space.

Acceleration of the EM algorithm in either case can be achieved through the methods of the turboem package, specified through the accelerate argument. However, note that these methods do not have the guaranteed convergence of the standard EM algorithm, particularly when the MLE is on the boundary of its (possibly constrained) parameter space.

Alternatively, an adaptive barrier method can be used by specifying method = "ab", which maximises the likelihood subject to constraints on the fitted values.

Value

logbin returns an object of class "logbin", which inherits from classes "glm" and "lm". The function summary logbin can be used to obtain or print a summary of the results.

The generic accessor functions coefficients, fitted.values and residuals can be used to extract various useful features of the value returned by logbin. Note that effects will not work.

An object of class "logbin" is a list containing the same components as an object of class "glm" (see the "Value" section of glm). It also includes:

loglik the maximised log-likelihood.

aic.c a small-sample corrected version of Akaike's An Information Criterion (Hur-

vich, Simonoff and Tsai, 1998). This is used by logbin. smooth to choose the

optimal number of knots for smooth terms.

xminmax the minimum and maximum observed values for each of the continuous covari-

ates, to help define the covariate space of the model.

As well as:

np.coefficients

estimated coefficients associated with the non-positive parameterisation corre-

sponding to the MLE.

nn.x non-negative model matrix associated with np.coefficients.

coefhist (if control\$coeftrace = TRUE), a matrix or list of matrices containing the co-

efficient estimates after each EM iteration.

Note

Due to the way in which the covariate space is defined in the CEM algorithm, models that include terms that are functionally dependent on one another — such as interactions and polynomials — may give unexpected results. Categorical covariates should always be entered directly as factors rather than dummy variables. 2-way interactions between factors can be included by calculating a new factor term that has levels corresponding to all possible combinations of the factor levels (see the Example). Non-linear relationships can be included by using logbin.smooth.

```

logbin.control

Auxiliary for Controlling logbin Fitting

Description

Auxiliary function for logbin fitting. Typically only used internally by nplbin, but may be used to construct a control argument to that function.

Usage

Arguments

bound.tol

positive tolerance specifying the interior of the parameter space. If the fitted model is more than bound. tol away from the boundary of the parameter space then it is assumed to be in the interior. This can allow the computational method to terminate early if an interior maximum is found. No early termination is attempted if bound. tol = Inf.

epsilon

positive convergence tolerance ϵ ; the estimates are considered to have converged when $\sqrt{\sum(\theta_{old}-\theta_{new})^2}/\sqrt{\sum\theta_{old}^2}<\epsilon$, where θ is the vector of parameter estimates

This should be smaller than bound. tol.

12 logbin.control

maxit	integer giving the maximum number of iterations (for a given parameterisation in the case of the CEM algorithm).
trace	number indicating level of output that should be produced. $>= 1$ gives output for each parameterisation, $>= 2$ gives output at each iteration.
coeftrace	logical indicating whether the coefficient history should be included as a component of the returned value (for method = "em" and method = "cem").

Details

This is used similarly to glm.control. The control argument of logbin is by default passed to the control argument of nplbin.

When trace is greater than zero, calls to cat produce the output. Hence, options(digits = *) can be used to increase the precision.

Value

A list with components named as the arguments.

Smooth Log-Binomial Regression

Description

logbin. smooth fits log-link binomial regression models using a stable CEM algorithm. It provides additional flexibility over logbin by allowing for smooth semi-parametric terms.

Usage

```
logbin.smooth(formula, mono = NULL, data, subset, na.action, offset,
              control = list(...), model = TRUE, model.logbin = FALSE,
          method = c("cem", "em"), accelerate = c("em", "squarem", "pem", "qn"),
              control.accelerate = list(), ...)
```

Arguments

formula	an object of	class	"formula"	(or	one	tha
---------	--------------	-------	-----------	-----	-----	-----

at can be coerced into that class): a symbolic description of the model to be fitted. The details of model specification are given under "Details". The model must contain an intercept and at least one semi-parametric term, included by using the B or Iso functions. Note that 2nd-order terms (such as interactions) or above are not currently supported (see

logbin).

a vector indicating which terms in formula should be restricted to have a monomono

tonically non-decreasing relationship with the outcome. May be specified as

names or indices of the terms.

Iso() terms are always monotonic.

an optional data frame, list or environment (or object coercible by as.data.frame data

> to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment (formula), typically the environment

from which logbin. smooth is called.

subset an optional vector specifying a subset of observations to be used in the fitting

process.

a function which indicates what should happen when the data contain NAs. The na.action

> default is set be the na.action setting of options, and is na.fail if that is unset. The 'factory-fresh' default is na. omit. Another possible value is NULL,

no action. Value na. exclude can be useful.

this can be used to specify an a priori known component to be included in the offset

> linear predictor during fitting. This should be NULL or a non-positive numeric vector of length equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if more than one is specified

their sum is used. See model.offset.

a list of parameters for controlling the fitting process, passed to logbin.control. control

mode1 a logical value indicating whether the model frame should be included as a com-

ponent of the returned value.

14 logbin.smooth

model.logbin a logical value indicating whether the fitted logbin object should be included

as a component of the returned value.

method a character string that determines which EM-type algorithm to use to find the

MLE: "cem" for the combinatorial EM algorithm, which cycles through a sequence of constrained parameter spaces, or "em" for a single EM algorithm

based on an overparameterised model.

Unlike logbin, methods "glm" and "ab" are not available because they do not

support the necessary monotonicity constraints.

accelerate a character string that determines the acceleration algorithm to be used, (par-

tially) matching one of "em" (no acceleration – the default), "squarem", "pem" or "qn". See turboem for further details. Note that "decme" is not permitted.

control.accelerate

a list of control parameters for the acceleration algorithm. See turboem for details of the parameters that apply to each algorithm. If not specified, the defaults

are used

... arguments to be used to form the default control argument if it is not supplied

directly.

Details

logbin. smooth performs the same fitting process as logbin, providing a stable maximum likelihood estimation procedure for log-link binomial GLMs, with the added flexibility of allowing semi-parametric B and Iso terms (note that logbin. smooth will stop with an error if no semi-parametric terms are specified in the right-hand side of the formula; logbin should be used instead).

The method partitions the parameter space associated with the semi-parametric part of the model into a sequence of constrained parameter spaces, and defines a fully parametric logbin model for each. The model with the highest log-likelihood is the MLE for the semi-parametric model (see Donoghoe and Marschner, 2015).

Value

An object of class "logbin.smooth", which contains the same objects as class "logbin" (the same as "glm"), as well as:

model.logbin if model.logbin is TRUE; the logbin object for the fully parametric model cor-

responding to the fitted model.

xminmax.smooth the minimum and maximum observed values for each of the smooth terms in the

model, to help define the covariate space.

full.formula the component from logbin:::interpret.logbin.smooth(formula) that con-

tains the formula term with any additional arguments to the B function removed.

knots a named list containing the knot vectors for each of the smooth terms in the

model.

nplbin

Non-Positive Log-Binomial Regression

Description

Finds the maximum likelihood estimate of a log-link binomial GLM using an EM algorithm, where each of the coefficients in the linear predictor is restricted to be non-positive.

Usage

Arguments

y binomial response. May be a single column of 0/1 or two columns, giving the number of successes and failures.

x non-negative covariate matrix.

16 nplbin

offset non-positive additive offset vector. The default is a vector of zeros.

start starting values for the parameter estimates. All elements must be less than or

equal to -control\$bound.tol.

Amat matrix that parameter estimates are left-multiplied by before testing for conver-

gence (e.g. to check reduced version of expanded parameter vector).

control a logbin.control object, which controls the fitting process.

accelerate a character string that determines the acceleration algorithm to be used, (par-

tially) matching one of "em" (no acceleration – the default), "squarem", "pem" or "qn". See turboem for further details. Note that "decme" is not permitted.

control.accelerate

a list of control parameters for the acceleration algorithm. See turboem for details of the parameters that apply to each algorithm. If not specified, the defaults

are used.

Details

This is a workhorse function for logbin, and runs the EM algorithm to find the constrained non-positive MLE associated with a log-link binomial GLM. See Marschner and Gillett (2012) for full details.

Value

A list containing the following components

coefficients the constrained non-positive maximum likelihood estimate of the parameters.

residuals the residuals at the MLE, that is y - fitted.values

fitted.values the fitted mean values.

rank the number of parameters in the model (named "rank" for compatibility — we

assume that models have full rank)

family included for compatibility — will always be binomial(log).

linear.predictors

the linear fit on link scale.

deviance up to a constant, minus twice the maximised log-likelihood.

aic a version of Akaike's An Information Criterion, minus twice the maximised log-

likelihood plus twice the number of parameters.

aic.c a small-sample corrected version of Akaike's An Information Criterion (Hur-

vich, Simonoff and Tsai, 1998).

null.deviance the deviance for the null model, comparable with deviance. The null model

will include the offset and an intercept.

iter the number of iterations of the EM algorithm used.
weights included for compatibility — a vector of ones.

prior.weights the number of trials associated with each binomial response.

df.residual the residual degrees of freedom.

df.null the residual degrees of freedom for the null model.

plot.logbin.smooth 17

converged logical. Did the EM algorithm converge?

boundary logical. Is the MLE on the boundary of the parameter space — i.e. are any of

the coefficients < control\$bound.tol?

loglik the maximised log-likelihood. nn.design the non-negative x matrix used.

Author(s)

Mark W. Donoghoe <markdonoghoe@gmail.com>.

This function is based on code from Marschner and Gillett (2012) written by Alexandra Gillett.

plot.logbin.smooth Default logbin.smooth Plotting

Description

The main use is to take a fitted logbin. smooth object produced by logbin. smooth and plot the component smooth functions that make it up, for specified values of the other covariates.

Alternatively, plots the model diagnostics usually provided by plot.lm.

Usage

```
## S3 method for class 'logbin.smooth'
plot(x, type = c("response", "link", "diagnostics"), at = data.frame(),
    knotlines = TRUE, nobs = 1000, ...)
```

Arguments

a fitted Togoth. Smooth object as produced by Togoth.	a fitted logbin. smooth object as produced by logbin. smooth.
---	---

type for "response" and "link", the type of prediction required. Note that, unlike

predict.logbin.smooth, "terms" is not a valid option.

for "diagnostics", plot. lm is called.

at a data frame containing the values at which the prediction should be evaluated.

The columns must contain the covariates in the model, and several rows may be provided (in which case, multiple lines are drawn on the same plot). Cannot be

missing or NULL.

18 predict.logbin

knotlines	logical; if vertical lines should be drawn on the plot to indicate the locations of the knots for B-spline terms.
nobs	the number of points which should be used to create the curve. These are placed evenly along the range of the observed covariate values from the original model.
	other graphics parameters to pass on to plotting commands, in particular any arguments to plot. lm (e.g., which).

Details

For each smooth covariate in the model of x, predict.logbin.smooth is used to obtain predicted values for the range of that covariate, with the other covariates remaining fixed at their values given in at. Several rows may be provided in at, in which case, one curve is drawn for each, and they are coloured using rainbow(nrow(at)). If the model contains a single smooth covariate and no other covariates, at may be provided as an empty data frame, data.frame().

Value

The function simply generates plots.

Note

If this function is too restrictive, it may be easier to use predict.logbin.smooth to get predictions for the dataset of your choice, and do the plotting manually.

predict.logbin

Predict Method for logbin Fits

Description

Obtains predictions from a fitted logbin object.

Usage

predict.logbin 19

Arguments

object a fitted object of class inheriting from "logbin".

newdata optionally, a data frame in which to look for variables with which to predict. If

omitted, the fitted linear predictors are used.

type the type of prediction required. The default is on the scale of the linear predic-

tors; the alternative "response" is on the scale of the response variable. The "terms" option returns a matrix giving the fitted values of each term in the

model formula on the linear predictor scale.

The value of this argument can be abbreviated.

terms with type = "terms" by default all terms are returned. A character vector spec-

ifies which terms are to be returned.

na.action function determining what should be done with missing values in newdata. The

default is to predict NA.

checkminmax logical indicating whether or not values of continuous covariates in newdata

should be checked to ensure they lie within the covariate space associated with the fitted model. Otherwise predicted values could lie outside the parameter

space.

... further arguments passed to or from other methods.

Details

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are treated is determined by the na.action argument of that fit. If na.action = na.omit, omitted cases will not appear in the residuals. If na.action = na.exclude they will appear, with residual value NA. See also napredict.

Value

A vector or matrix of predictions. For type = "terms", this is a matrix with a column per term, and may have an attribute "constant".

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

```

predict.logbin.smooth Predict Method for logbin.smooth Fits

Description

Obtains predictions from a fitted logbin. smooth object.

Usage

Arguments

object a fitted object of class inheriting from "logbin.smooth".

newdata optionally, a data frame in which to look for variables with which to predict. If

omitted, the fitted linear predictors are used.

type the type of prediction required. The default is on the scale of the linear predic-

tors; the alternative "response" is on the scale of the response variable. The "terms" option returns a matrix giving the fitted values of each term in the

model formula on the linear predictor scale.

The value of this argument can be abbreviated.

terms with type = "terms" by default all terms are returned. A character vector spec-

ifies which terms are to be returned.

na.action function determining what should be done with missing values in newdata. The

default is to predict NA.

. . . further arguments passed to or from other methods.

Details

predict.logbin.smooth constructs the underlying basis functions for smooth variables in newdata and runs predict.logbin to obtain predictions. Note that if values of smooth covariates in newdata are outside the covariate space of object, an error will be returned.

If newdata is omitted, the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are treated is determined by the na.action argument of that fit. If na.action = na.omit, omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also napredict.

Value

A vector or matrix of predictions. For type = "terms", this is a matrix with a column per term, and may have an attribute "constant".

summary.logbin 21

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

summary.logbin

Summarising logbin Model Fits

Description

These functions are all methods for class logbin or summary.logbin objects.

Usage

Arguments

object	an object of class "logbin", usually from a call to logbin or logbin.smooth.
X	an object of class "summary.logbin", usually from a call to summary.logbin.
correlation	logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed. $$
digits	the number of significant digits to use when printing.
signif.stars	logical; if TRUE, 'significance stars' are printed for each coefficient.
	further arguments passed to or from other methods.

22 summary.logbin

Details

These perform the same function as summary.glm and print.summary.glm, producing similar results for logbin models. print.summary.logbin additionally prints the small-sample corrected AIC (aic.c), and the number of EM iterations for the parameterisation corresponding to the MLE.

The dispersion used in calculating standard errors is fixed as 1.

Value

summary.logbin returns an object of class "summary.logbin", a list with components

the component from object. call the component from object. family deviance the component from object. aic the component from object. aic.c the component from object. df.residual the component from object. null.deviance the component from object. df.null the component from object. the component from object. iter

deviance.resid the deviance residuals: see residuals.glm.

coefficients the matrix of coefficients, standard errors, z-values and p-values.

aliased included for compatibility — always FALSE.

dispersion the inferred/estimated dispersion.

df included for compatibility — a 3-vector of the number of coefficients, the num-

ber of residual degrees of freedom, and the number of coefficients (again).

cov.unscaled the unscaled (dispersion = 1) estimated covariance matrix of the estimated co-

efficients. NaN if object\$boundary == TRUE.

cov.scaled ditto, scaled by dispersion.

correlation if correlation is TRUE, the estimated correlations of the estimated coefficients.

NaN if object\$boundary == TRUE.

Note

If object\$boundary == TRUE, the standard errors of the coefficients are not valid, and a matrix of NaNs is returned by vcov.logbin. If the MLE is not on the boundary but the model contains parameters with monotonicity constraints, the standard errors do not take this into account and should be used with caution.

vcov.logbin

Calculate Variance-Covariance Matrix for a Fitted logbin Model Object

Description

Returns the variance-covariance matrix of the main parameters of a fitted logbin model object.

Usage

```
## S3 method for class 'logbin'
vcov(object, ...)
```

Arguments

object an object of class "logbin", usually from a call to logbin or logbin.smooth.
... additional arguments for method functions.

Details

An equivalent method to vcov, to use with logbin models.

Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the coef method.

Note

If object\$boundary == TRUE, the standard errors of the coefficients are not valid, and a matrix of NaNs is returned.
