

Package ‘nestedLogit’

July 22, 2025

Title Nested Dichotomy Logistic Regression Models

Version 0.3.2

Date 2023-06-06

Description Provides functions for specifying and fitting nested dichotomy logistic regression models for a multi-category response and methods for summarising and plotting those models. Nested dichotomies are statistically independent, and hence provide an additive decomposition of tests for the overall 'polytomous' response. When the dichotomies make sense substantively, this method can be a simpler alternative to the standard 'multinomial' logistic model which compares response categories to a reference level. See: J. Fox (2016), ``Applied Regression Analysis and Generalized Linear Models'', 3rd Ed., ISBN 1452205663.

as.data.frame.predictNestedLogit
<i>Convert a Predicted Objects to a data.frame</i>

Description

These functions provide simple ways to convert the results of `predict.nestedLogit` to a data frame in a consistent format for plotting and other actions.

Usage

```
## S3 method for class 'predictNestedLogit'  
as.data.frame(x, row.names = NULL, optional = FALSE, ...)
```

Arguments

x	a "predictNestedLogit" object
row.names	row.names for result (for conformity with generic; not currently used)
optional	logical. If TRUE, setting row names and converting column names (to syntactic names: see make.names is optional
...	other arguments (unused)

Value

- For `predict(..., model="nested")` (the default), returns a data frame containing the values of predictors along with the columns response, p, se.p, logit, se.logit.
- For `predict(..., model="dichotomies")`, returns a data frame containing the values of predictors along with the columns response, logit, and se.logit.

Examples

```
data("Womenlf", package = "carData")
comparisons <- logits(work=dichotomy("not.work", c("parttime", "fulltime")),
                      full=dichotomy("parttime", "fulltime"))

wlf.nested <- nestedLogit(partic ~ hincome + children,
                          dichotomies = comparisons,
                          data=Womenlf)
# get predicted values for a grid of `hincome` and `children`
new <- expand.grid(hincome=seq(0, 45, length=10),
                  children=c("absent", "present"))

pred.nested <- predict(wlf.nested, new)
plotdata <- as.data.frame(pred.nested)
str(plotdata)

# Predicted logit values for the dichotomies
pred.dichot <- predict(wlf.nested, new, model = "dichotomies")
plotlogit <- as.data.frame(pred.dichot)
str(plotlogit)
```

broomMethods

Broom Related Methods

Description

These functions give compact summaries of a "nestedLogit" object

`glance` Construct a single row summaries for the dichotomies "nestedLogit" model.

`tidy` Summarizes the terms in "nestedLogit" model.

Usage

```
## S3 method for class 'nestedLogit'
glance(x, ...)
```

```
## S3 method for class 'nestedLogit'
tidy(x, ...)
```

Arguments

`x` an object of class "nestedLogit".

`...` arguments to be passed down.

Value

- `glance` returns a tibble containing one row of fit statistics for each dichotomy, labeled response. See [glance](#) for details.
- `tidy` returns a tibble containing coefficient estimates and test statistics for the combinations of response and term. See [tidy](#) for details.

See Also

[nestedMethods](#), [glance](#), [tidy](#)

Examples

```
data("Womenlf", package = "carData")
m <- nestedLogit(partic ~ hincome + children,
  dichotomies = logits(work=dichotomy("not.work",
    working=c("parttime", "fulltime")),
    full=dichotomy("parttime", "fulltime")),
  data=Womenlf)

# one-line summaries
broom::glance(m)
# coefficients and tests
broom::tidy(m)
```

Effect.nestedLogit *Effect Displays for Nested Logit Models*

Description

Computes effects (in the sense of the **effects** package—see, in particular, [Effect](#))—for "nestedLogit" models, which then can be used with other functions in the **effects** package, for example, [predictorEffects](#) and to produce effect plots.

Usage

```
## S3 method for class 'nestedLogit'
Effect(
  focal.predictors,
  mod,
  confidence.level = 0.95,
  fixed.predictors = NULL,
  ...
)
```

Arguments

focal.predictors
a character vector of the names of one or more of the predictors in the model, for which the effect display should be computed.

mod
a "nestedLogit" model object.

confidence.level
for point-wise confidence bands around the effects (the default is 0.95).

GSS

*Data From the U.S. General Social Survey 1972-2016***Description**

This data set is drawn from the U.S. General Social Survey (GSS) for years between 1972 and 2016.

Usage

```
data("GSS", package = "nestedLogit")
```

Format

A data frame with 44091 rows and 3 columns.

parentdeg A factor representing parents' attained level of education (highest "degree" obtained), recording the higher of mother's and father's education, with levels "l.t.highschool", "highschool", "college", and "graduate".

degree The respondent's level of education, a factor with the same levels as parentdeg.

year The year of the survey, between 1972 and code2016.

Source

General Social Survey, NORC, The University of Chicago <https://www.norc.org/Research/Projects/Pages/general-social-survey.aspx>.

See Also

[nestedLogit](#).

Examples

```
round(100*with(GSS, prop.table(table(degree, parentdeg), 2)))
m.GSS <- nestedLogit(degree ~ parentdeg*year,
                     continuationLogits(c("l.t.highschool", "highschool",
                                           "college", "graduate")),
                     data=GSS)
car::Anova(m.GSS)
summary(m.GSS)
```

HealthInsuranceChoice of Health Insurance Product

Description

A company recently introduced a new health insurance provider for its employees. At the beginning of the year the employees had to choose one of three (or four) different health plan products from this provider to best suit their needs.

This dataset was modified from its original source (McNulty, 2022) for the present purposes by adding a fourth choice, sampled randomly from the original three.

Usage

```
data("HealthInsurance", package = "nestedLogit")
```

Format

A data frame with 1448 rows and 7 columns.

product Choice among three products, a factor with levels "A", "B", and "C".

product4 Choice among four products, a factor with levels "A", "B", "C", and "D".

age The age of the individual, in years.

household The number of people living with the individual in the same household.

position_level Position level in the company at the time the choice was made, where 1 is the lowest level and 5 is the highest, a numeric vector.

gender The gender of the individual, a factor with levels "Female" and "Male".

absent The number of days the individual was absent from work in the year prior to the choice,

[nestedLogit](#).

Examples

```
lbinary <- logits(AB_CD = dichotomy(c("A", "B"), c("C", "D")),
                 A_B   = dichotomy("A", "B"),
                 C_D   = dichotomy("C", "D"))
as.matrix(lbinary)
health.nested <- nestedLogit(product4 ~ age + gender * household + position_level,
                             dichotomies = lbinary, data = HealthInsurance)
car::Anova(health.nested)
coef(health.nested)
```

models

Extract Binary Logit Models from a nestedLogit Object

Description

models is used to extract "glm" objects representing binary logit models from a "nestedLogit" object.

Usage

```
models(model, select, as.list = FALSE)

## S3 method for class 'nestedLogit'
models(model, select, as.list = FALSE)
```

Arguments

model	a "nestedLogit" model.
select	a numeric or character vector giving the number(s) or names(s) of one or more binary logit models to be extracted from model; if absent, a list of all of the binary logits models in model is returned.
as.list	if TRUE (the default is FALSE) and one binary logit model is selected, return the "glm" object in a one-element named list; otherwise a single model is returned directly as a "glm" object; when more than one binary logit model is selected, the corresponding "glm" objects are <i>always</i> returned as a named list.

Value

model returns either a single "glm" object (see [glm](#)) or a list of "glm" objects, each representing a binary logit model.

Examples

```
data("Womenlf", package = "carData")
comparisons <- logits(work=dichotomy("not.work",
                                     working=c("parttime", "fulltime")),
                     full=dichotomy("parttime", "fulltime"))
m <- nestedLogit(partic ~ hincome + children,
                 dichotomies = comparisons,
                 data=Womenlf)

# extract a binomial logit model
models(m, "work")
# use that to plot residuals
plot(density(residuals(models(m, "work"))))
```

Description

Various methods for testing hypotheses about nested logit models.

Anova Calculates type-II or type-III analysis-of-variance tables for "nestedLogit" objects; see [Anova](#) in the **car** package.

anova Computes sequential analysis of variance (or deviance) tables for one or more fitted "nestedLogit" objects; see [anova](#).

linearHypothesis Computes Wald tests for linear hypotheses; see [linearHypothesis](#) in the **car** package.

logLik Returns the log-likelihood and degrees of freedom for the nested-dichotomies model. (and through it [AIC](#) and [BIC](#) model-comparison statistics).

Usage

```
## S3 method for class 'nestedLogit'
Anova(mod, ...)

## S3 method for class 'Anova.nestedLogit'
print(x, ...)

## S3 method for class 'nestedLogit'
linearHypothesis(model, ...)

## S3 method for class 'nestedLogit'
anova(object, object2, ...)

## S3 method for class 'anova.nestedLogit'
print(x, ...)

## S3 method for class 'nestedLogit'
logLik(object, ...)
```

Arguments

... arguments to be passed down. In the case of **linearHypothesis**, the second argument is typically the `hypothesis.matrix`. See the Details section of [linearHypothesis](#). In the case of **anova**, additional sequential "nestedLogit" models.

`x`, `object`, `object2`, `mod`, `model` in most cases, an object of class "nestedLogit".

Value

- The Anova and anova methods return objects of class "Anova.nestedLogit" and "anova.nestedLogit", respectively, each of which contains a list of "anova" objects (see [anova](#)) and is usually printed.
- The linearHypothesis method is called for its side effect, printing the result of linear hypothesis tests, and invisibly returns NULL.
- The logLik method returns an object of class "logLik" (see [logLik](#)).

# define continuation dichotomies for level of education
cont.dichots <- continuationLogits(c("l.t.highschool",
                                     "highschool",
                                     "college",
                                     "graduate"))

# fit a nested model for the GSS data examining education degree in relation to parent & year
m <- nestedLogit(degree ~ parentdeg + year,
                 cont.dichots,
                 data=GSS)

# Anova and anova tests
car::Anova(m) # type-II (partial) tests

anova(update(m, . ~ . - year), m) # model comparison

# Wald test
car::linearHypothesis(m, c("parentdeghighschool", "parentdegcollege",
                          "parentdeggraduate"))

# log-likelihood, AIC, and BIC
logLik(m)
AIC(m)
BIC(m)
```

Description

Fit a related set of binary logit models via the `glm` function to nested dichotomies, comprising a model for the polytomy. A polytomous response with m categories can be analyzed using $m - 1$ binary logit comparisons. When these comparisons are nested, the $m - 1$ sub-models are statistically independent. Therefore, the likelihood chi-square statistics for the sub-models are additive and give overall tests for a model for the polytomy. This method was introduced by Fienberg (1980), and subsequently illustrated by Fox(2016) and Friendly & Meyer (2016).

`dichotomy` and `logits` are helper functions to construct the dichotomies.

`continuationLogits` constructs a set of $m - 1$ logit comparisons, called continuation logits, for an ordered response. With $m = 4$ levels, say, A, B, C, D, considered low to high: The first contrasts B, C, D against A. The second ignores A and contrasts C, D against B. The second ignores A, B and contrasts D against C.

Usage

```
nestedLogit(formula, dichotomies, data, subset = NULL, contrasts = NULL, ...)

logits(...)

dichotomy(...)

continuationLogits(levels, names, prefix = "above_")
```

Arguments

<code>formula</code>	a model formula with the polytomous response on the left-hand side and the usual linear-model-like specification on the right-hand side.
<code>dichotomies</code>	specification of the logits for the nested dichotomies, constructed by the <code>logits</code> and <code>dichotomy</code> functions, or <code>continuationLogits</code> . Alternatively, the dichotomies can be specified as a nested (i.e., recursive) list, the elements of which can be given optional names. See Details.
<code>data</code>	a data frame with the data for the model; unlike in most statistical modeling functions, the data argument is required. Cases with NAs in any of the variables appearing in the model formula will be removed with a Note message.
<code>subset</code>	a character string specifying an expression to fit the model to a subset of the data; the default, <code>NULL</code> , uses the full data set.
<code>contrasts</code>	an optional list of contrast specification for specific factors in the model; see <code>lm</code> for details.
<code>...</code>	for <code>nestedLogit</code> , optional named arguments to be passed to <code>glm</code> ; for <code>logits</code> , definitions of the nested logits—with each named argument specifying a dichotomy; for <code>dichotomy</code> , two character vectors giving the levels defining the dichotomy; the vectors can optionally be named.
<code>levels</code>	A character vector of set of levels of the variables or a number specifying the numbers of levels (in which case, uppercase letters will be use for the levels).
<code>names</code>	Names to be assigned to the dichotomies; if absent, names will be generated from the levels.

prefix a character string (default: "above_") used as a prefix to the names of the continuation dichotomies.

Details

A *dichotomy* for a categorical variable is a comparison of one subset of levels against another subset. A set of dichotomies is *nested*, if after an initial dichotomy, all subsequent ones are *within* the groups of levels lumped together in earlier ones. Nested dichotomies correspond to a binary tree of the successive divisions.

For example, for a 3-level response, a first dichotomy could be {A}, {B, C} and then the second one would be just {B}, {C}. Note that in the second dichotomy, observations with response A are treated as NA.

The function `dichotomy` constructs a *single* dichotomy in the required form, which is a list of length 2 containing two character vectors giving the levels defining the dichotomy. The function `logits` is used to create the set of dichotomies for a response factor. Alternatively, the nested dichotomies can be specified more compactly as a nested (i.e., recursive) list with optionally named elements; for example, `list(air="plane", ground=list(public=list("train", "bus"), private="car"))`.

The function `continuationLogits` provides a convenient way to generate all dichotomies for an ordered response. For an ordered response with $m = 4$ levels, say, A, B, C, D, considered low to high: The dichotomy first contrasts B, C, D against A. The second ignores A and contrasts C, D against B. The second ignores A, B and contrasts D against C.

Value

`nestedLogit` returns an object of class "nestedLogit" containing the following elements:

- `models`, a named list of (normally) $m - 1$ "glm" objects, each a binary logit model for one of the $m - 1$ nested dichotomies representing the m -level response.
- `formula`, the model formula for the nested logit models.
- `dichotomies`, the "dichotomies" object defining the nested dichotomies for the model.
- `data.name`, the name of the data set to which the model is fit, of class "name".
- `data`, the data set to which the model is fit.
- `subset`, a character representation of the subset argument or "NULL" if the argument isn't specified.
- `contrasts`, the contrasts argument or NULL if the argument isn't specified.
- `contrasts.print` a character representation of the contrasts argument or "NULL" if the argument isn't specified.

`logits` and `continuationLogits` return objects of class "dichotomies" and `c("continuationDichotomies" "dichotomies")`, respectively, which are two-elements lists, each element containing a list of two character vectors representing a dichotomy. `dichotomy` returns a list of two character vectors representing a dichotomy.

 nestedMethods

Methods for "nestedLogit" and Related Objects

Description

Various methods for processing "nestedLogit" and related objects. Most of these are the standard methods for a model-fitting function.

`coef`, `vcov` Return the coefficients and their variance-covariance matrix respectively.

`update` Re-fit a "nestedLogit" model with a change in any of the formula, dichotomies, data, subset, or contrasts, arguments.

`predict`, `fitted` Computes predicted values from a fitted "nestedLogit" model.

`confint` Compute point-wise confidence limits for predicted response-category probabilities or logits.

`glance` Construct a single row summaries for the dichotomies "nestedLogit" model.

`tidy` Summarizes the terms in "nestedLogit" model.

Usage

```
## S3 method for class 'nestedLogit'
print(x, ...)

## S3 method for class 'nestedLogit'
summary(object, ...)

## S3 method for class 'summary.nestedLogit'
print(x, ...)

## S3 method for class 'dichotomies'
print(x, ...)

## S3 method for class 'nestedLogit'
predict(object, newdata, model = c("nested", "dichotomies"), ...)

## S3 method for class 'predictNestedLogit'
print(x, n = min(10L, nrow(x$p)), ...)

## S3 method for class 'predictNestedLogit'
confint(
  object,
  parm = c("prob", "logit"),
```

```

    level = 0.95,
    conf.limits.logit = TRUE,
    ...
)

## S3 method for class 'predictDichotomies'
print(x, n = 10L, ...)

## S3 method for class 'nestedLogit'
fitted(object, model = c("nested", "dichotomies"), ...)

## S3 method for class 'nestedLogit'
coef(object, as.matrix = TRUE, ...)

## S3 method for class 'nestedLogit'
vcov(object, as.matrix = FALSE, ...)

## S3 method for class 'nestedLogit'
update(object, formula, dichotomies, data, subset, contrasts, ...)

## S3 method for class 'dichotomies'
as.matrix(x, ...)

## S3 method for class 'dichotomies'
as.character(x, ...)

## S3 method for class 'continuationDichotomies'
as.matrix(x, ...)

as.dichotomies(x, ...)

## S3 method for class 'matrix'
as.dichotomies(x, ...)

```

Arguments

x, object	in most cases, an object of class "nestedLogit".
...	arguments to be passed down.
newdata	For the predict method, a data frame containing combinations of values of the predictors at which fitted probabilities (or other quantities) are to be computed.
model	For the predict and fitted methods, either "nested" (the default), in which case fitted probabilities under the nested logit model are returned, or "dichotomies", in which case <code>predict.glm</code> is invoked for each binary logit model fit to the nested dichotomies and a named list of the results is returned.
n	For the print method of <code>predict.nestedLogit</code> or <code>predictDichotomies</code> , an integer or "all" to control how many rows are printed for each of the probabilities of response categories, corresponding logits and their standard errors.

<code>parm</code>	For the <code>confint</code> method, one of "prob" or "logit", indicating whether to generate confidence intervals for probabilities or logits of the responses.
<code>level</code>	Confidence level for the <code>confint</code> method
<code>conf.limits.logit</code>	When <code>parm = "prob"</code> ????
<code>as.matrix</code>	if TRUE (the default for <code>coef</code>) return coefficients as a matrix with one column for each nested dichotomy, or coefficient covariances as a matrix with one row and column for each combination of dichotomies and coefficients; if FALSE (the default for <code>vcov</code>), return a list of coefficients or coefficient covariances with one element for each dichotomy.
<code>formula</code>	optional updated model formula.
<code>dichotomies</code>	optional updated dichotomies object.
<code>data</code>	optional updated data argument
<code>subset</code>	optional updated subset argument.
<code>contrasts</code>	optional updated contrasts argument.

Details

The `predict` method provides predicted values for two representations of the model. `model = "nested"` gives the fitted probabilities for each of the response categories. `model = "dichotomies"` gives the fitted log odds for each binary logit models in the dichotomies.

Value

- The `coef` and `vcov` methods return either matrices or lists of regression coefficients and their covariances, respectively.
- The `update` method returns an object of class "nestedLogit" (see [nestedLogit](#)) derived from the original nested-logit model.
- The `predict` and `fitted` methods return an object of class "predictNested" or "predictDichotomies", which contain the predicted probabilities, predicted logits, and other information, such as standard errors of predicted values, and, if supplied, the newdata on which predictions are based.
- The `summary` method returns an object of class "summary.nestedLogit", which is a list of summaries of the [glm](#) objects that comprise the nested-dichotomies model; the object is normally printed.
- The methods for `as.matrix`, `as.character`, and `as.dichotomies` coerce various objects to matrices, character vectors, and dichotomies objects.
- The various `print` methods invisibly return their `x` arguments.

                  year=c(1972, 2016))
fit <- predict(m, newdata=new)
cbind(new, fit) # fitted probabilities at specific values of predictors

# predicted logits for dichotomies
predictions <- predict(m, newdata=new, model="dichotomies")
predictions
```

Description

A **plot** method for "nestedLogit" objects produced by the **nestedLogit** function. Fitted probabilities under the model are plotted for each level of the polytomous response variable, with one of the explanatory variables on the horizontal axis and other explanatory variables fixed to particular values. By default, a 95% pointwise confidence envelope is added to the plot.

Usage

```
## S3 method for class 'nestedLogit'
plot(
  x,
  x.var,
  others,
  n.x.values = 100L,
  xlab = x.var,
  ylab = "Fitted Probability",
  main,
  cex.main = 1,
  digits.main = getOption("digits") - 2L,
  font.main = 1L,
  pch = 1L:length(response.levels),
  lwd = 3,
  lty = 1L:length(response.levels),
  col = palette()[1L:length(response.levels)],
  legend = TRUE,
  legend.inset = 0.01,
  legend.location = "topleft",
  legend.bty = "n",
  conf.level = 0.95,
  conf.alpha = 0.3,
  ...
)
```

Arguments

<code>x</code>	an object of "nestedLogit" produced by nestedLogit .
<code>x.var</code>	quoted name of the variable to appear on the x-axis; if omitted, the first predictor in the model is used.
<code>others</code>	a named list of values for the other variables in the model, that is, other than <code>x.var</code> ; if any other predictor is omitted, it is set to an arbitrary value—the mean for a numeric predictor or the first level or value of a factor, character, or logical predictor; only one value may be specified for each variable in <code>others</code> .
<code>n.x.values</code>	the number of evenly spaced values of <code>x.var</code> at which to evaluate fitted probabilities to be plotted (default 100).
<code>xlab</code>	label for the x-axis (defaults to the value of <code>x.var</code>).
<code>ylab</code>	label for the y-axis (defaults to "Fitted Probability").
<code>main</code>	main title for the graph (if missing, constructed from the variables and values in <code>others</code>).
<code>cex.main</code>	size of main title (see par).
<code>digits.main</code>	number of digits to retain when rounding values for the main title.
<code>font.main</code>	font for main title (see par).
<code>pch</code>	plotting characters (see par).

lwd	line width (see par).
lty	line types (see par).
col	line colors (see par).
legend	if TRUE (the default), add a legend for the response levels to the graph.
legend.inset	default 0.01 (see legend).
legend.location	position of the legend (default "topleft", see legend).
legend.bty	the type of box to be drawn around the legend. The allowed values are "o" (the default) and "n".
conf.level	the level for pointwise confidence envelopes around the predicted response probabilities; the default is 0.95. If NULL, the confidence envelopes are suppressed.
conf.alpha	the opacity of the confidence envelopes; the default is 0.3.
...	arguments to be passed to matplot .

Value

NULL Used for its side-effect of producing a plot

Examples

```
data("Womenlf", package = "carData")
m <- nestedLogit(partic ~ hincome + children,
                 logits(work=dichotomy("not.work", c("parttime", "fulltime")),
                       full=dichotomy("parttime", "fulltime")),
                 data=Womenlf)
plot(m, legend.location="top")
op <- par(mfcol=c(1, 2), mar=c(4, 4, 3, 1) + 0.1)
plot(m, "hincome", list(children="absent"),
     xlab="Husband's Income", legend=FALSE)
plot(m, "hincome", list(children="present"),
     xlab="Husband's Income")
par(op)
```
