pcaone	<i>Randomized Singular Value Decomposition Algorithm with Window-based Power Iterations from PCAone (Li et al 2022).</i>
--------	--

Description

The Randomized Singular Value Decomposition (RSVD) computes the near-optimal low-rank approximation of a rectangular matrix using a fast probabilistic algorithm.

Usage

```
pcaone(
  A,
  k = NULL,
  p = 7,
  q = 10,
  sdist = "normal",
  method = "alg2",
  windows = 64,
  shuffle = FALSE
)
```

Arguments

A	array_like; a real/complex (m, n) input matrix (or data frame) to be decomposed.
k	integer; specifies the target rank of the low-rank decomposition. k should satisfy $k \ll \min(m, n)$.
p	integer, optional; number of additional power iterations (by default $p = 7$).
q	integer, optional; oversampling parameter (by default $q = 10$).
sdist	string $c('unif', 'normal')$, optional; specifies the sampling distribution of the random test matrix: 'unif' : Uniform $[-1, 1]$. 'normal' (default) : Normal $\sim N(0, 1)$.
method	string $c('alg1', 'alg2')$, optional; specifies the different variation of the randomized singular value decomposition: : 'alg1' : single pass RSVD with power iterations in PCAone referred to algorithm1. 'alg2' (default): window based RSVD in PCAone referred to algorithm2.

windows	integer, optional; the number of windows for 'alg2' method. must be a power of 2 (by default <i>windows</i> = 64).
shuffle	logical, optional; if shuffle the rows of input tall matrix or not. recommended for algorithm 2 (by default <i>shuffle</i> = <i>FALSE</i>).

Details

The singular value decomposition (SVD) plays an important role in data analysis, and scientific computing. Given a rectangular (m, n) matrix A , and a target rank $k < \min(m, n)$, the SVD factors the input matrix A as

$$A = U_k \text{diag}(d_k) V_k^T$$

The k left singular vectors are the columns of the real or complex unitary matrix U . The k right singular vectors are the columns of the real or complex unitary matrix V . The k dominant singular values are the entries of d , and non-negative and real numbers.

q is an oversampling parameter to improve the approximation. A value of at least 10 is recommended, and $q = 10$ is set by default.

The parameter p specifies the number of power (subspace) iterations to reduce the approximation error. The power scheme is recommended, especially when the singular values decay slowly. However, computing power iterations increases the computational costs. Even though most RSVD implementations recommend $p = 3$ power iterations by default, it's always sufficient to run only few power iterations where our window-based power iterations ('alg2') come to play. We recommend using *windows* = 64 and $p \geq 7$ for *pcaone* algorithm2. As it is designed for large dataset, we recommend using 'alg2' when $\max(n, m) > 5000$.

If $k > (\min(n, m)/4)$, a deterministic partial or truncated [svd](#) algorithm might be faster.

Value

pcaone returns a list containing the following three components:

- d** array_like;
singular values; vector of length (k) .
- u** array_like;
left singular vectors; (m, k) or (m, nu) dimensional array.
- v** array_like;
right singular vectors; (n, k) or (n, nv) dimensional array.

Note

The singular vectors are not unique and only defined up to sign. If a left singular vector has its sign changed, changing the sign of the corresponding right vector gives an equivalent decomposition.

Examples

```
library('pcaone')
mat <- matrix(rnorm(100*20000), 100, 20000)
res <- pcaone(mat, k = 10, p = 7, method = "alg2")
str(res)
res <- pcaone(mat, k = 10, p = 7, method = "alg1")
str(res)
```
