Package 'sampling'

July 23, 2025

Version 2.11

Date 2025-07-10

Title Survey Sampling

Description Functions to draw random samples using different sampling schemes are available. Functions are also provided to obtain (generalized) calibration weights, different estimators, as well some variance estimators.

Imports MASS, lpSolve, utils

Depends R (>= 3.5.0)

License GPL (>= 2)

balancedcluster *Balanced cluster*

Description

Selects a balanced cluster sample.

Usage

```
balancedcluster(X,m,cluster,selection=1,comment=TRUE,method=1)
```

Arguments

X	matrix of auxiliary variables on which the sample must be balanced.
m	number of clusters to be selected.
cluster	vector of integers that defines the clusters.
selection	1, selection of the clusters with probabilities proportional to size, 2, selection of the clusters with equal probabilities.
comment	a comment is written during the execution if comment is TRUE.
method	the used method in the function samplecube.

Value

Returns a matrix containing the vector of inclusion probabilities and the selected sample.

See Also

samplecube, fastflightcube, landingcube

Examples

```
############
## Example 1
############
# definition of the clusters; there are 15 units in 3 clusters
cluster=c(1,1,1,1,1,2,2,2,2,2,3,3,3,3,3)
# matrix of balancing variables
X=cbind(c(1,2,3,4,5,6,7,8,9,10,11,12,13,14,15))
# selection of 2 clusters
s=balancedcluster(X,2,cluster,2,TRUE)
# the sample of clusters with the inclusion probabilities of the clusters
s
# the selected clusters
unique(cluster[s[,1]==1])
# the selected units
(1:length(cluster))[s[,1]==1]
# with the probabilities
s[s[,1]==1,2]
```

```
############
## Example 2
############
data(MU284)

s=balancedcluster(X,10,MU284$CL,1,TRUE)
cluster=MU284$CL
# the selected clusters
unique(cluster[s[,1]==1])
# the selected units
(1:length(cluster))[s[,1]==1]
# with the probabilities
s[s[,1]==1,2]
```

`balancedstratification` *Balanced stratification*

Description

Selects a stratified balanced sample (a vector of 0 and 1). Firstly, the flight phase is applied in each stratum. Secondly, the strata are aggregated and the flight phase is applied on the whole population. Finally, the landing phase is applied on the whole population.

Usage

```
balancedstratification(X,strata,pik,comment=TRUE,method=1)
```

Arguments

`X`	matrix of auxiliary variables on which the sample must be balanced.
`strata`	vector of integers that specifies the stratification.
`pik`	vector of inclusion probabilities.
`comment`	a comment is written during the execution if `comment` is `TRUE`.
`method`	the used method in the function `samplecube`.

balancedtwostage *Balanced two-stage sampling*

Description

Selects a balanced two-stage sample.

Usage

```
balancedtwostage(X,selection,m,n,PU,comment=TRUE,method=1)
```

Arguments

X	matrix of auxiliary variables on which the sample must be balanced.
selection	1, for simple random sampling without replacement at each stage, 2, for self-weighting two-stage selection.
m	number of primary sampling units to be selected.
n	number of second-stage sampling units to be selected.

PU	vector of integers that defines the primary sampling units.
comment	a comment is written during the execution if comment is TRUE.
method	the used method in the function samplecube.

Value

The function returns a matrix whose columns are the following five vectors: the selected second-stage sampling units (0 - unselected, 1 - selected), the final inclusion probabilities, the selected primary sampling units, the inclusion probabilities of the first stage, the inclusion probabilities of the second stage.

belgianmunicipalities *The Belgian municipalities population*

Description

This data provides information about the Belgian population of July 1, 2004 compared to that of July 1, 2003, and some financial information about the municipality incomes at the end of 2001.

Usage

```
data(belgianmunicipalities)
```

Format

A data frame with 589 observations on the following 17 variables:

Commune municipality name.

INS 'Institut National de statistique' code.

Province province number.

Arrondiss administrative division number.

Men04 number of men on July 1, 2004.

Women04 number of women on July 1, 2004.

Tot04 total population on July 1, 2004.

Men03 number of men on July 1, 2003.

Women03 number of women on July 1, 2003.

Tot03 total population on July 1, 2003.

Diffmen number of men on July 1, 2004 minus the number of men on July 1, 2003.

Diffwom number of women on July 1, 2004 minus the number of women on July 1, 2003.

DiffTOT difference between the total population on July 1, 2004 and on July 1, 2003.

TaxableIncome total taxable income in euros in 2001.

Totaltaxation total taxation in euros in 2001.

averageincome average of the income-tax return in euros in 2001.

medianincome median of the income-tax return in euros in 2001.

`calib` *g-weights of the calibration estimator*

Description

Computes the g-weights of the calibration estimator. The g-weights should lie in the specified bounds for the truncated and logit methods.

Usage

```
calib(Xs,d,total,q=rep(1,length(d)),method=c("linear","raking","truncated",
"logit"),bounds=c(low=0,upp=10),description=FALSE,max_iter=500)
```

Arguments

`Xs`	matrix of calibration variables.
`d`	vector of initial weights.
`total`	vector of population totals.
`q`	vector of positive values accounting for heteroscedasticity; the variation of the g-weights is reduced for small values of q.
`method`	calibration method (linear, raking, logit, truncated).
`bounds`	vector of bounds for the g-weights used in the truncated and logit methods; 'low' is the smallest value and 'upp' is the largest value.
`description`	if description=TRUE, summary of initial and final weights are printed, and their boxplots and histograms are drawn; by default, its value is FALSE.
`max_iter`	maximum number of iterations in the Newton's method.

Details

The argument *method* implements the methods given in the paper of Deville and Särndal(1992).

Value

Returns the vector of g-weights.

`calibev` *Calibration estimator and its variance estimation*

Description

Computes the calibration estimator of the population total and its variance estimation using the residuals' method.

Usage

```
calibev(Ys,Xs,total,pikl,d,g,q=rep(1,length(d)),with=FALSE,EPS=1e-6)
```

Arguments

`Ys`	vector of interest variable; its size is n, the sample size.
`Xs`	matrix of sample calibration variables.
`total`	vector of population totals for calibration.
`pikl`	matrix of joint inclusion probabilities of the sample units.
`d`	vector of initial weights of the sample units.
`g`	vector of g-weights; its size is n, the sample size.

q	vector of positive values accounting for heteroscedasticity; its size is n, the sample size.
with	if TRUE, the variance estimation takes into account the initial weights d; otherwise, the final weights w=g*d are taken into account; by default, its value is FALSE.
EPS	tolerance in checking the calibration; by default, its value is 1e-6.

Details

If with is TRUE, the following formula is used

$$\widehat{Var}(\widehat{Ys}) = \sum_{k \in s} \sum_{\ell \in s} ((\pi_{k\ell} - \pi_k \pi_\ell)/\pi_{k\ell})(d_k e_k)(d_\ell e_\ell)$$

else

$$\widehat{Var}(\widehat{Ys}) = \sum_{k \in s} \sum_{\ell \in s} ((\pi_{k\ell} - \pi_k \pi_\ell)/\pi_{k\ell})(w_k e_k)(w_\ell e_\ell)$$

where e_k denotes the residual of unit k.

Value

The function returns two values:

cest	the calibration estimator,
evar	its estimated variance.

```

---

checkcalibration *Check calibration*

Description

Checks the validity of the calibration. In some cases, the computed g-weights do not allow calibration and the calibration estimators do not exist.

Usage

```
checkcalibration(Xs, d, total, g, EPS=1e-6)
```

Arguments

Xs	matrix of calibration variables.
d	vector of initial weights.
total	vector of population totals.
g	vector of g-weights.
EPS	control value used to check the calibration, by default equal to 1e-6.

Details

In the case where calibration is not possible, the 'value' indicates the difference in obtaining the calibration.

Value

The function returns the following three objects:

`message`	a message concerning the calibration,
`result`	TRUE if the calibration is possible and FALSE, otherwise.
`value`	value of max(abs(tr-total)/total, which is used as criterium to validate the calibration, where tr=crossprod(Xs, g*d). If the `total` vector contains zeros, the value is max(abs(tr-total)).

See Also

`calib`

Examples

```
# matrix of auxiliary variables
Xs=cbind(c(1,1,1,1,1,0,0,0,0,0),c(0,0,0,0,0,1,1,1,1,1),c(1,2,3,4,5,6,7,8,9,10))
# inclusion probabilities

g=calib(Xs,d=1/pik,total,method="raking")
# check if the calibration is possible
checkcalibration(Xs,d=1/pik,total,g)
```

---

cleanstrata *Clean strata*

Description

Renumbers a variable of stratification (categorical variable). The strata receive a number from 1 to the last stratum number. The empty strata are suppressed. This function is used in 'balancedstratification'.

Usage

```
cleanstrata(strata)
```

Arguments

`strata`	vector of stratum numbers.

See Also

balancedstratification

Examples

```
# definition of the stratification variable
strata=c(-2,3,-2,3,4,4,4,-2,-2,3,4,0,0,0)
# renumber the strata
cleanstrata(strata)
```

---

cluster *Cluster sampling*

Description

Cluster sampling with equal/unequal probabilities.

Usage

```
cluster(data, clustername, size, method=c("srswor","srswr","poisson",
"systematic"),pik,description=FALSE)
```

Arguments

data	data frame or data matrix; its number of rows is N, the population size.
clustername	the name of the clustering variable.
size	sample size.
method	method to select clusters; the following methods are implemented: simple random sampling without replacement (srswor), simple random sampling with replacement (srswr), Poisson sampling (poisson), systematic sampling (systematic); if the method is not specified, by default the method is "srswor".
pik	vector of inclusion probabilities or auxiliary information used to compute them; this argument is only used for unequal probability sampling (Poisson, systematic). If an auxiliary information is provided, the function uses the inclusionprobabilities function for computing these probabilities.
description	a message is printed if its value is TRUE; the message gives the number of selected clusters, the number of units in the population and the number of selected units. By default, the value is FALSE.

Value

The function returns a data set with the following information: the selected clusters, the identifier of the units in the selected clusters, the final inclusion probabilities for these units (they are equal for the units included in the same cluster). If method is "srswr", the number of replicates is also given.

Examples

```
############
## Example 1
############
# Uses the swissmunicipalities data to draw a sample of clusters
data(swissmunicipalities)
# the variable 'REG' has 7 categories in the population
# it is used as clustering variable
# the sample size is 3; the method is simple random sampling without replacement
cl=cluster(swissmunicipalities,clustername=c("REG"),size=3,method="srswor")
# extracts the observed data
# the order of the columns is different from the order in the initial database
getdata(swissmunicipalities, cl)
############
## Example 2
############
# the same data as in Example 1
# the sample size is 3; the method is systematic sampling
# the pik vector is randomly generated using the U(0,1) distribution
cl_sys=cluster(swissmunicipalities,clustername=c("REG"),size=3,method="systematic",
pik=runif(7))
# extracts the observed data
getdata(swissmunicipalities,cl_sys)
```

---

disjunctive *Disjunctive combination*

Description

Transforms a categorical variable into a matrix of indicators. The values of the categorical variable are integer numbers (positive or negative).

Usage

```
disjunctive(strata)
```

Arguments

strata	vector of integer numbers.

See Also

balancedstratification

Examples

```
# definition of the variable of stratification
strata=c(-2,3,-2,3,4,4,4,-2,-2,3,4,0,0,0)
# computation of the matrix
disjunctive(strata)
```

`fastflightcube` *Fast flight phase for the cube method*

Description

Executes the fast flight phase of the cube method (algorithm of Chauvet and Tillé, 2005, 2006). The data are sorted following the argument `order`. Inclusion probabilities equal to 0 or 1 are tolerated.

Usage

```
fastflightcube(X,pik,order=1,comment=TRUE)
```

Arguments

`X`	matrix of auxiliary variables on which the sample must be balanced.
`pik`	vector of inclusion probabilities.
`order`	1, the data are randomly arranged, 2, no change in data order, 3, the data are sorted in decreasing order.
`comment`	a comment is written during the execution if `comment` is `TRUE`.

pikstar
```

---

gencalib *g-weights of the generalized calibration estimator*

Description

Computes the g-weights of the generalized calibration estimator. The g-weights should lie in the specified bounds for the truncated and logit methods.

Usage

```
gencalib(Xs,Zs,d,total,q=rep(1,length(d)),method=c("linear","raking","truncated","logit"),
bounds=c(low=0,upp=10),description=FALSE,max_iter=500,C=1)
```

Arguments

Xs	matrix of calibration variables.
Zs	matrix of instrumental variables with same dimension as Xs.
d	vector of initial weights.
total	vector of population totals.
q	vector of positive values accounting for heteroscedasticity; the variation of the g-weights is reduced for small values of q.
method	calibration method (linear, raking, logit, truncated).
bounds	vector of bounds for the g-weights used in the truncated and logit methods; 'low' is the smallest value and 'upp' is the largest value.
description	if description=TRUE, summary of initial and final weights are printed, and their boxplots and histograms are drawn; by default, its value is FALSE.
max_iter	maximum number of iterations in the Newton's method.
C	value of the centering constant, by default equals 1.

Details

The generalized calibration or the instrument vector method computes the g-weights $g_k = F(\lambda' z_k)$, where z_k is a vector with values defined for $k \in s$ (or $k \in r$ where r is the set of respondents) and sharing the dimension of the specified auxiliary vector x_k. The vectors z_k and x_k have to be stronlgy correlated. The vector λ is determined from the calibration equation $\sum_{k\in s} d_k g_k x_k = \sum_{k\in U} x_k$ or $\sum_{k\in r} d_k g_k x_k = \sum_{k\in U} x_k$. The function F plays the same role as in the calibration method (see calib). If Xs=Zs the calibration method is obtain. If the method is "logit" the g-weights will be centered around the constant C, with low<C<upp. In the calibration method C=1 (see calib).

Value

The function returns the vector of g-weights.

getdata *Get data*

Description

Extracts the observed data from a data frame (a population). The function is used after a sample has been drawn from this population.

Usage

```
getdata(data, m)
```

Arguments

data	population data frame or data matrix; its number of rows is N, the population size.
m	vector of selected units or sample data frame.

See Also

srswor, UPsystematic, strata, cluster, mstage

Examples

```

Hajekestimator *The Hajek estimator*

Description

Computes the Hájek estimator of the population total or population mean.

Usage

```
Hajekestimator(y,pik,N=NULL,type=c("total","mean"))
```

Arguments

y	vector of the variable of interest; its length is equal to n, the sample size.
pik	vector of the first-order inclusion probabilities; its length is equal to n, the sample size.
N	population size; N is only used for the total estimator; for the mean estimator its value is NULL.
type	the estimator type: total or mean.

See Also

HTestimator

Examples

```
# Belgian municipalities data
data(belgianmunicipalities)
# Computes the inclusion probabilities
pik=inclusionprobabilities(belgianmunicipalities$Tot04,200)
N=length(pik)
n=sum(pik)
# Defines the variable of interest
y=belgianmunicipalities$TaxableIncome
# Draws a Poisson sample of expected size 200
s=UPpoisson(pik)
# Computes the Hajek estimator of the population mean
Hajekestimator(y[s==1],pik[s==1],type="mean")
# Computes the Hajek estimator of the population total
Hajekestimator(y[s==1],pik[s==1],N=N,type="total")
```

Hajekstrata *The Hajek estimator for a stratified design*

Description

Computes the Hájek estimator of the population total or population mean for a stratified design.

Usage

```
Hajekstrata(y,pik,strata,N=NULL,type=c("total","mean"),description=FALSE)
```

Arguments

y	vector of the variable of interest; its length is equal to n, the sample size.
pik	vector of the first-order inclusion probabilities for the sampled units; its length is equal to n, the sample size.
strata	vector of size n, with elements indicating the unit stratum.
N	vector of population sizes of strata; N is only used for the total estimator; for the mean estimator its value is NULL.
type	the estimator type: total or mean.
description	if TRUE, the estimator is printed for each stratum; by default, FALSE.

Hajekstrata(x$Pop020,x$Prob,x$Stratum,N,type="total",description=TRUE)
```

`HTestimator` *The Horvitz-Thompson estimator*

Description

Computes the Horvitz-Thompson estimator of the population total.

Usage

```
HTestimator(y,pik)
```

Arguments

`y`	vector of the variable of interest; its length is equal to n, the sample size.
`pik`	vector of the first-order inclusion probabilities; its length is equal to n, the sample size.

See Also

`UPtille`

Examples

pik=inclusionprobabilities(Tot04,200)
N=length(pik)
n=sum(pik)
# draws a Poisson sample of expected size 200
s=UPpoisson(pik)
# Horvitz-Thompson estimator of the total of TaxableIncome
HTestimator(TaxableIncome[s==1],pik[s==1])
detach(belgianmunicipalities)
```

HTstrata *The Horvitz-Thompson estimator for a stratified design*

Description

Computes the Horvitz-Thompson estimator of the population total for a stratified design.

Usage

```
HTstrata(y,pik,strata,description=FALSE)
```

Arguments

y	vector of the variable of interest; its length is equal to n, the sample size.
pik	vector of the first-order inclusion probabilities for the sampled units; its length is equal to n, the sample size.
strata	vector of size n, with elements indicating the unit stratum.
description	if TRUE, the estimator is printed for each stratum; by default, FALSE.

# computes the HT estimator of the total of Pop020
HTstrata(x$Pop020,x$Prob,x$Stratum,description=TRUE)
```

`inclusionprobabilities` *Inclusion probabilities*

Description

Computes the first-order inclusion probabilities from a vector of positive numbers (for a probability proportional-to-size sampling design). Their sum is equal to n, the sample size.

Usage

```
inclusionprobabilities(a,n)
```

Arguments

a	vector of positive numbers.
n	sample size.

See Also

`inclusionprobastrata`

Examples

```
############
## Example 1
############
# a vector of positive numbers
a=1:20
# inclusion probabilities for a sample size n=12
inclusionprobabilities(a,12)
############
## Example 2
############
# Computation of the inclusion probabilities proportional to the number
# of inhabitants in each municipality of the Belgian municipalities data.
data(belgianmunicipalities)
pik=inclusionprobabilities(belgianmunicipalities$Tot04,200)
# the first-order inclusion probabilities for each municipality
data.frame(pik=pik,name=belgianmunicipalities$Commune)
# the sum is equal to the sample size
sum(pik)
```

inclusionprobastrata *Inclusion probabilities for a stratified design*

Description

Computes the inclusion probabilities for a stratified design. The inclusion probabilities are equal in each stratum.

Usage

```
inclusionprobastrata(strata,nh)
```

Arguments

strata	vector that defines the strata.
nh	vector of the number of selected units in each stratum.

See Also

balancedstratification

Examples

```
# the strata
strata=c(1,1,1,1,1,2,2,2,2,2,2,3,3,3,3,3,3,3)
# sample size in each stratum
nh=c(2,3,3)
# inclusion probabilities for each stratum
pik=inclusionprobastrata(strata,nh)
#check for each stratum
cbind(strata, pik)
```

landingcube *Landing phase for the cube method*

Description

Landing phase of the cube method using linear programming.

Usage

```
landingcube(X,pikstar,pik,comment=TRUE)
```

Arguments

X	matrix of auxiliary variables on which the sample must be balanced.
pikstar	vector obtained at the end of the flight phase.
pik	vector of inclusion probabilities.
comment	a comment is written during the execution if comment is TRUE.

```

---

mstage *Multistage sampling*

Description

Implements multistage sampling with equal/unequal probabilities.

Usage

```
mstage(data, stage=c("stratified","cluster",""), varnames, size,
method=c("srswor","srswr","poisson","systematic"), pik, description=FALSE)
```

Arguments

data	data frame or data matrix; its number of rows is N, the population size.
stage	list of sampling types at each stage; the possible values are: "stratified", "cluster" and "" (without stratification or clustering). For multistage element sampling, this argument is not necessary.
varnames	list of stratification or clustering variables.
size	list of sample sizes (in the order in which the samples appear in the multistage sampling).
method	list of methods to select units at each stage; the following methods are implemented: simple random sampling without replacement (srswor), simple random sampling with replacement (srswr), Poisson sampling (poisson), systematic sampling (systematic); if the method is not specified, by default the method is "srswor". The method can be different at each stage.
pik	list of selection probabilities or auxiliary information used to compute them; this argument is only used for unequal probability sampling (Poisson, systematic). If an auxiliary information is provided, the function uses the inclusionprobabilities function for computing these probabilities.
description	a message is printed if its value is TRUE; the message gives the number of selected units and the number of the units in the population. By default, its value is FALSE.

Details

The data should be sorted in ascending order by the columns given in the varnames argument before applying the function. Use, for example, data[order(data$state,data$region),].

Value

The function returns a list, which contains the stages (if m is this list, the stage i is m$'i' etc) and the following information:

ID_unit	the identifier of selected units at each stage.
Prob_number_stage	the inclusion probability at stage 'number'.
Prob	the final unit inclusion probability given in the last stage; it is the product of unit inclusion probabilities at each stage.

MU284 *The MU284 population*

Description

This data is from Särndal et al (1992), see Appendix B, p. 652.

Usage

```
data(MU284)
```

Format

A data frame with 284 observations on the following 11 variables.

LABEL identifier number from 1 to 284.

P85 1985 population (in thousands).

P75 1975 population (in thousands).

RMT85 revenues from 1985 municipal taxation (in millions of kronor).

CS82 number of Conservative seats in municipal council.

SS82 number of Social-Democratic seats in municipal council.

S82 total number of seats in municipal council.

ME84 number of municipal employees in 1984.

REV84 real estate values according to 1984 assessment (in millions of kronor).

REG geographic region indicator.

CL cluster indicator (a cluster consists of a set of neighboring).

```

`postest` *Poststratified estimator*

Description

Computes the poststratified estimator of the population total.

Usage

```
postest(data, y, pik, NG, description=FALSE)
```

Arguments

`data`	data frame or data matrix; its number of rows is n, the sample size.
`y`	vector of the variable of interest; its length is equal to n, the sample size.
`pik`	vector of the first-order inclusion probabilities for the sampled units; its length is equal to n, the sample size.
`NG`	vector of population frequency in each group G; for stratified sampling with poststratification, NG is a matrix of population frequency in each cell GH.
`description`	if TRUE, the estimator is printed for each poststratum; by default, FALSE.

```

`poststrata` *Postratification*

Description

Poststratification using several criteria.

Usage

```
poststrata(data, postnames = NULL)
```

Arguments

`data`	data frame or data matrix; its number of rows is n, the sample size.
`postnames`	vector of poststratification variables.

Value

The function	produces an object, which contains the following information:
data	the final data frame with a new column ('poststratum') containg the unit poststratum.
npost	the number of poststrata.

See Also

postest

Examples

```
# Example from An and Watts (New SAS procedures for Analysis of Sample Survey Data)
# generates artificial data (a 235X3 matrix with 3 columns: state, region, income).
# the variable "state" has 2 categories ('nc' and 'sc').
# the variable "region" has 3 categories (1, 2 and 3).
# the income variable is randomly generated
data=rbind(matrix(rep("nc",165),165,1,byrow=TRUE),matrix(rep("sc",70),70,1,byrow=TRUE))
data=cbind.data.frame(data,c(rep(1,100), rep(2,50), rep(3,15), rep(1,30),rep(2,40)),

#  3  15   0
# postratification using two criteria: state and region
poststrata(data,postnames=c("state","region"))
```

---

ratioest *Ratio estimator*

Description

Computes the ratio estimator of the population total.

Usage

```
ratioest(y,x,Tx,pik)
```

Arguments

y	vector of the variable of interest; its length is equal to n, the sample size.
x	vector of auxiliary information; its length is equal to n, the sample size.
Tx	population total of x.
pik	vector of the first-order inclusion probabilities; its length is equal to n, the sample size.

Value

The function returns the value of the ratio estimator.

See Also

regest

Examples

```
# population
data(MU284)
# there are 3 outliers which are deleted from the population
MU281=MU284[MU284$RMT85<=3000,]
attach(MU281)
# computes the inclusion probabilities using the variable P85; sample size 120
pik=inclusionprobabilities(P85,120)
# defines the variable of interest
y=RMT85
# defines the auxiliary information
x=CS82
# draws a systematic sample of size 120
s=UPsystematic(pik)
# computes the ratio estimator of the total of RMT85
ratioest(y[s==1],x[s==1],sum(x),pik[s==1])
detach(MU281)
```

---

ratioest_strata *Ratio estimator for a stratified design*

Description

Computes the ratio estimator of the population total for a stratified design. The ratio estimator of a total is the sum of ratio estimator in each stratum.

Usage

```
ratioest_strata(y,x,TX_strata,pik,strata,description=FALSE)
```

Arguments

y	vector of the variable of interest; its length is equal to n, the sample size.
x	vector of auxiliary information; its length is equal to n, the sample size.
TX_strata	vector of population x-total in each stratum; its length is equal to the number of strata.
pik	vector of the first-order inclusion probabilities; its length is equal to n, the sample size.
strata	vector of size n, with elements indicating the unit stratum.
description	if TRUE, the ratio estimator in each stratum is printed; by default, it is FALSE.

Value

The function returns the value of the ratio estimator.

```

`rec99` *The 1999 census data*

Description

This data provides census information about the municipalities of the Haute-Garonne department, France, with less than 10000 inhabitants in 1999.

Usage

```
data(rec99)
```

Format

A data frame with 554 observations on the following 10 variables:

CODE_N municipality code.

COMMUNE municipality name.

BVQ_N code of the Daily Life Basin to which the municipality belongs.

POPSDC99 number of inhabitants.

LOG number of dwellings.

LOGVAC number of vacant dwellings.

STRATLOG a four-modality variable which equals 1 if the municipality has less than 100 dwellings, 2 if it has between 100 and 299 dwellings, 3 if it has between 300 and 999 dwellings and 4 if it has 1000 dwellings or more.

surf_m2 surface in square meters.

lat_centre geographical latitude of the center.

lon_centre geographical longitude of the center.

NAME_3 regional administration (prefecture) name; a three-modality variable: Muret, Saint-Gaudens, Toulouse.

Source

For the first 8 variables, 'Institut national de la statistique et des Etudes Economiques', France (http://www.insee.fr). The geographical positions are available under the Open Database License ("OpenStreetMap contributors"). https://www.openstreetmap.org/copyright

Examples

```
data(rec99)
hist(rec99$LOG)

regest *Regression estimator*

Description

Computes the regression estimator of the population total, using the design-based approach. The underling regression model is a model without intercept.

Usage

```
regest(formula,Tx,weights,pikl,n,sigma=rep(1,length(weights)))
```

Arguments

formula	regression model formula (y~x).
Tx	population total of x, the auxiliary variable.
weights	vector of the weights; its length is equal to n, the sample size.
pikl	matrix of joint inclusion probabilities for the sample.
n	the sample size.
sigma	vector of positive values accounting for heteroscedasticity.

Value

The function returns a list with following components:

regest	value of the regression estimator.
coefficients	vector of estimated beta coefficients.
std_error	estimated standard error of the estimated coefficients.
t_value	t-values associated to the coefficients.
p_value	p-values associated to the coefficients.

cov_mat	covariance matrix of the estimated coefficients.
weights	specified weights.
y	response variable.
x	model matrix.

regest_strata *Regression estimator for a stratified design*

Description

Computes the regression estimator of the population total for a stratified sampling, using the design-based approach. The same regression model is used for all strata. The underling regression model is a model without intercept.

Usage

```
regest_strata(formula,weights,Tx_strata,strata,pikl,
sigma=rep(1,length(weights)),description=FALSE)
```

Arguments

formula	regression model formula (y~x).
weights	vector of the weights; its length is equal to n, the sample size.
Tx_strata	population total of x, the auxiliary variable.
strata	vector of stratum identificator.
pikl	joint inclusion probabilities for the sample.
sigma	vector of positive values accounting for heteroscedasticity.
description	if TRUE, the following components are printed for each stratum: the Horvitz-Thompson estimator, the estimated beta coefficients, their estimated standard error, t_values, p_values, and the covariance matrix. By default, FALSE.

Value

The function returns the value of the regression estimator computed as the sum of the stratum estimators.

See Also

regest

Examples

```
# generates artificial data
y=rgamma(10,3)
x=y+rnorm(10)
Stratum=c(1,1,2,2,2,3,3,3,3,3)
# population size
N=200
# sample size
n=10
# assume proportional allocation, nh/Nh=n/N
# joint inclusion probabilities (for the sample)
pikl=matrix(n*(n-1)/(N*(N-1)),n,n)
diag(pikl)=n/N
regest_strata(formula=y~x-1,weights=rep(N/n,n),Tx_strata=c(50,30,40),
strata=Stratum,pikl,description=TRUE)
```

rhg *Response homogeneity groups*

Description

Computes the response homogeneity groups and the response probability for each unit in these groups.

Usage

```
rhg(X,selection)
```

Arguments

X	sample data frame; it should contain the columns 'ID_unit' and 'status'; 'ID_unit' denotes the unit identifier (a number); 'status' is a 1/0 variable denoting the response/non-response of a unit.
selection	vector of variable names in X used to construct the groups.

Details

Into a response homogeneity group, the reponse probability is the same for all units. Data are missing at random within groups, conditionally on the selected sample.

Value

The initial sample data frame and also the following components:

rhgroup	the response homogeneity group for each unit.
prob_response	the response probability for each unit; for the units with status=0, this probability is 0.

# creates the response homogeneity groups using the 'town' variable
rhg(Xs,selection="town")
```

`rhg_strata` *Response homogeneity groups for a stratified sampling*

Description

Computes response homogeneity groups and the corresponding response probability for each unit into a group, for a stratified sampling.

Usage

```
rhg_strata(X,selection)
```

Arguments

`X`	sample data frame; it should contain the columns 'ID_unit','Stratum', and 'status'; 'ID_unit' denotes the unit identifier (a number); 'Stratum' denotes the unit stratum; 'status' is a 1/0 variable denoting the response/non-response of a unit in the sample.
`selection`	vector of variable names in X used to construct the groups.

Details

Into a response homogeneity group, the reponse probability is the same for all units. Data are missing at random within groups, conditionally on the selected sample.

Value

The initial sample data frame and also the following components:

`rhgroup`	response homogeneity group for each unit, conditionally on its stratum.
`prob_response`	response probability for each unit; for the units with status=0, this probability is 0.

# computes the response homogeneity groups using the 'classincome' and 'sex' variables
rhg_strata(s1,selection=c("classincome","sex"))
```

`rmodel` *Response probability using logistic regression*

Description

Computes the response probabilities using logistic regression for non-response adjustment. For stratified sampling, the same logistic model is used for all strata.

Usage

```
rmodel(formula,weights,X)
```

Arguments

formula	regression model formula (y~x).
weights	vector of weights; its length is equal to n, the sample size.
X	sample data frame.

Value

The function returns the sample data frame with a new column 'prob_resp', which contains the response probabilities.

```

`samplecube` *Sample cube method*

Description

Selects a balanced sample (a vector of 0 and 1) or an almost balanced sample. Firstly, the flight phase is applied. Next, if needed, the landing phase is applied on the result of the flight phase.

Usage

```
samplecube(X,pik,order=1,comment=TRUE,method=1)
```

Arguments

`X`	matrix of auxiliary variables on which the sample must be balanced.
`pik`	vector of inclusion probabilities.
`order`	1, the data are randomly arranged, 2, no change in data order, 3, the data are sorted in decreasing order.
`comment`	a comment is written during the execution if `comment` is `TRUE`.
`method`	1, for a landing phase by linear programming, 2, for a landing phase by suppression of variables.

`srswor` *Simple random sampling without replacement*

Description

Draws a simple random sampling without replacement of size n (equal probabilities, fixed sample size, without replacement).

Usage

```
srswor(n,N)
```

Arguments

n	sample size.
N	population size.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise).

See Also

srswr

Examples

```
############
## Example 1
############
#select a sample
s=srswor(3,10)
#the sample is
which(s==1)
############
## Example 2
############
data(belgianmunicipalities)
Tot=belgianmunicipalities$Tot04
name=belgianmunicipalities$Commune
n=200
#select a sample
s=srswor(n,length(Tot))
#the sample is
which(s==1)
#names of the selected units
as.vector(name[s==1])
```

---

srswor1 *Selection-rejection method*

Description

Draws a simple random sampling without replacement of size n using the selection-rejection method (equal probabilities, fixed sample size, without replacement).

Usage

```
srswor1(n,N)
```

Arguments

n	sample size.
N	population size.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise).

References

srswr *Simple random sampling with replacement*

Description

Draws a simple random sampling with replacement of size n (equal probabilities, fixed sample size, with replacement).

Usage

```
srswr(n,N)
```

Arguments

n	sample size.
N	population size.

Value

Returns a vector of size N, the population size. Each element k of this vector indicates the number of replicates of unit k in the sample.

See Also

UPmultinomial

Examples

```
s=srswr(3,10)
#the selected units are
which(s!=0)
#with the number of replicates
s[s!=0]
```

---

strata *Stratified sampling*

Description

Stratified sampling with equal/unequal probabilities.

Usage

```
strata(data, stratanames=NULL, size, method=c("srswor","srswr","poisson",
"systematic"), pik,description=FALSE)
```

Arguments

data	data frame or data matrix; its number of rows is N, the population size.
stratanames	vector of stratification variables.
size	vector of stratum sample sizes (in the order in which the strata are given in the input data set).
method	method to select units; the following methods are implemented: simple random sampling without replacement (srswor), simple random sampling with replacement (srswr), Poisson sampling (poisson), systematic sampling (systematic); if "method" is missing, the default method is "srswor".
pik	vector of inclusion probabilities or auxiliary information used to compute them; this argument is only used for unequal probability sampling (Poisson and systematic). If an auxiliary information is provided, the function uses the inclusionprobabilities function for computing these probabilities.
description	a message is printed if its value is TRUE; the message gives the number of selected units and the number of the units in the population. By default, the value is FALSE.

Details

The data should be sorted in ascending order by the columns given in the stratanames argument before applying the function. Use, for example, data[order(data$state,data$region),].

Value

The function produces an object, which contains the following information:

ID_unit	the identifier of the selected units.
Stratum	the unit stratum.
Prob	the unit inclusion probability.

`swissmunicipalities` *The Swiss municipalities population*

Description

This population provides information about the Swiss municipalities in 2003.

Usage

```
data(swissmunicipalities)
```

Format

A data frame with 2896 observations on the following 22 variables:

CT Swiss canton.

REG Swiss region.

COM municipality number.

Nom municipality name.

HApoly municipality area.

Surfacesbois wood area.

Surfacescult area under cultivation.

Alp mountain pasture area.

Airbat area with buildings.

Airind industrial area.

P00BMTOT number of men.

P00BWTOT number of women.

Pop020 number of men and women aged between 0 and 19.

Pop2040 number of men and women aged between 20 and 39.

Pop4065 number of men and women aged between 40 and 64.

Pop65P number of men and women aged between 65 and over.

H00PTOT number of households.

H00P01 number of households with 1 person.

H00P02 number of households with 2 persons.

H00P03 number of households with 3 persons.

H00P04 number of households with 4 persons.

POPTOT total population.

Source

Swiss Federal Statistical Office.

`UPbrewer` *Brewer sampling*

Description

Uses the Brewer's method to select a sample of units (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPbrewer(pik,eps=1e-06)
```

Arguments

pik	vector of the inclusion probabilities.
eps	the control value, by default equal to 1e-06; it is used to control pik (pik>eps & pik < 1-eps).

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise).

References

#the sample is
which(s==1)
```

UPmaxentropy *Maximum entropy sampling*

Description

Maximum entropy sampling with fixed sample size and unequal probabilities (or Conditional Poisson sampling) is implemented by means of a sequential method (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPmaxentropy(pik)
UPmaxentropypi2(pik)
UPMEqfromw(w,n)
UPMEpikfromq(q)
UPMEpiktildefrompik(pik,eps=1e-6)
UPMEsfromq(q)
UPMEpik2frompikw(pik,w)
```

Arguments

n	sample size.
pik	vector of prescribed inclusion probabilities.
eps	tolerance in the Newton's method; by default is 1E-6.
q	matrix of the conditional selection probabilities for the sequential algorithm.
w	parameter vector of the maximum entropy design.

Details

The maximum entropy sampling maximizes the entropy criterion:

$$I(p) = -\sum_s p(s)\log[p(s)]$$

The main procedure is UPmaxentropy which selects a sample (a vector of 0 and 1) from a given vector of inclusion probabilities. The procedure UPmaxentropypi2 returns the matrix of joint inclusion probabilities from the first-order inclusion probability vector. The other procedures are intermediate steps. They can be useful to run simulations as shown in the examples below. The procedure UPMEpiktildefrompik computes the vector of the inclusion probabilities (denoted pikt) of a Poisson sampling from the vector of the inclusion probabilities of the maximum entropy sampling. The maximum entropy sampling is the conditional design given the fixed sample size. The vector w can be easily obtained by w=pikt/(1-pikt). Once piktilde and w are deduced from pik, a matrix of selection probabilities q can be derived from the sample size n and the vector w via UPMEqfromw. Next, a sample can be selected from q using UPMEsfromq. In order to generate several samples, it is more efficient to compute the matrix q (which needs some calculation), and then to use the procedure UPMEsfromq. The vector of the inclusion probabilities can be recomputed from q using UPMEpikfromq, which also checks the numerical precision of the algorithm. The procedure UPMEpik2frompikw computes the matrix of the joint inclusion probabilities from q and w.

`UPmidzuno` *Midzuno sampling*

Description

Uses the Midzuno's method to select a sample of units (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPmidzuno(pik,eps=1e-6)
```

Arguments

`pik`	vector of the inclusion probabilities.
`eps`	control value, by default equal to 1e-6.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise). The value 'eps' is used to control pik (pik>eps & pik < 1-eps).

```

UPmidzunopi2 *Joint inclusion probabilities for Midzuno sampling*

Description

Computes the joint (second-order) inclusion probabilities for Midzuno sampling.

Usage

```
UPmidzunopi2(pik)
```

Arguments

pik	vector of the first-order inclusion probabilities.

Value

Returns a NxN matrix of the following form: the main diagonal contains the first-order inclusion probabilities for each unit k in the population; elements (k,l) are the joint inclusion probabilities of units k and l, with k not equal to l. N is the population size.

UPminimalsupport *Minimal support sampling*

Description

Uses the minimal support method to select a sample of units (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPminimalsupport(pik)
```

Arguments

pik	vector of the inclusion probabilities.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise).

`UPmultinomial` *Multinomial sampling*

Description

Uses the Hansen-Hurwitz method to select a sample of units (unequal probabilities, with replacement, fixed sample size).

Usage

```
UPmultinomial(pik)
```

Arguments

`pik`	vector of the inclusion probabilities.

Value

Returns a vector of size N, the population size. Each element k of this vector indicates the number of replicates of unit k in the sample.

References

Hansen, M. and Hurwitz, W. (1943), On the theory of sampling from finite populations. *Annals of Mathematical Statistics*, 14:333-362.

Examples

```
#defines the prescribed inclusion probabilities

#or use
rep((1:length(pik))[s!=0],s[s!=0])
```

UPopips *Order pips sampling*

Description

Implements order πps sampling (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPopips(lambda,type=c("pareto","uniform","exponential"),eps=1e-6)
```

Arguments

lambda	vector of working inclusion probabilities or target ones.
type	the type of order sampling (pareto, uniform, exponential).
eps	control value, by default equal to 1e-6.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise). The value eps is used to control lambda (lambda>eps & lambda < 1-eps).

Examples

```
#define the working inclusion probabilities
lambda<-c(0.2,0.7,0.8,0.5,0.4,0.4)
#draw a Pareto sample
s<-UPopips(lambda, type="pareto")
#the sample is
which(s==1)
```

`UPpivotal` *Pivotal sampling*

Description

Selects an unequal probability sample using the pivotal method (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPpivotal(pik,eps=1e-6)
```

Arguments

`pik`	vector of the inclusion probabilities.
`eps`	control value, by default equal to 1e-6.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise). The value eps is used to control pik (pik>eps & pik < 1-eps).

```

UPpoisson *Poisson sampling*

Description

Draws a Poisson sample using a prescribed vector of first-order inclusion probabilities (unequal probabilities, without replacement, random sample size).

Usage

```
UPpoisson(pik)
```

Arguments

pik	vector of the first-order inclusion probabilities.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise).

getdata(name,s)
```

`UPrandompivotal` *Random pivotal sampling*

Description

Selects a sample using the pivotal method, when the order of the population units is random (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPrandompivotal(pik,eps=1e-6)
```

Arguments

`pik`	vector of the inclusion probabilities.
`eps`	control value, by default equal to 1e-6.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise). The value 'eps' is used to control pik (pik>eps and pik<1-eps).

```

UPrandomsystematic *Random systematic sampling*

Description

Selects a sample using the systematic method, when the order of the population units is random (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPrandomsystematic(pik,eps=1e-6)
```

Arguments

pik	vector of the inclusion probabilities.
eps	control value, by default equal to 1e-6.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise). The value 'eps' is used to control pik (pik>eps and pik<1-eps).

#the sample is
(1:length(pik))[s==1]
```

`UPsampford` *Sampford sampling*

Description

Uses the Sampford's method to select a sample of units (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPsampford(pik,eps=1e-6, max_iter=500)
```

Arguments

`pik`	vector of the inclusion probabilities.
`eps`	control value, by default equal to 1e-6.
`max_iter`	maximum number of iterations in the algorithm.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise). The value eps is used to control pik (pik>eps & pik < 1-eps). The sample size must be small with respect to the population size; otherwise, the selection time can be very long.

`UPsystematicpi2` *Joint inclusion probabilities for systematic sampling*

Description

Computes the joint (second-order) inclusion probabilities for systematic sampling.

Usage

```
UPsystematicpi2(pik)
```

Arguments

`pik`	vector of the first-order inclusion probabilities.

Value

Returns a NxN matrix of the following form: the main diagonal contains the first-order inclusion probabilities for each unit k in the population; elements (k,l) are the joint inclusion probabilities of units k and l, with k not equal to l. N is the population size.

References

Madow, W.G. (1949), On the theory of systematic sampling, II, *Annals of Mathematical Statistics*, 20, 333-354.

`UPsystematic`

Examples

```
#define the prescribed inclusion probabilities
pik=c(0.2,0.7,0.8,0.5,0.4,0.4)
#matrix of joint inclusion probabilities
UPsystematicpi2(pik)
```

UPtille *Tille sampling*

Description

Uses the Tillé's method to select a sample of units (unequal probabilities, without replacement, fixed sample size).

Usage

```
UPtille(pik,eps=1e-6)
```

Arguments

pik	vector of the inclusion probabilities.
eps	control value, by default equal to 1e-6.

Value

Returns a vector (with elements 0 and 1) of size N, the population size. Each element k of this vector indicates the status of unit k (1, unit k is selected in the sample; 0, otherwise). The value eps is used to control pik (pik>eps & pik < 1-eps).

`UPtillepi2` *Joint inclusion probabilties for Tille sampling*

Description

Computes the joint (second-order) inclusion probabilities for Tillé sampling.

Usage

```
UPtillepi2(pik,eps=1e-6)
```

Arguments

`pik`	vector of the first-order inclusion probabilities.
`eps`	control value, by default equal to 1e-6.

Value

Returns a NxN matrix of the following form: the main diagonal contains the first-order inclusion probabilities for each unit k in the population; elements (k,l) are the joint inclusion probabilities of units k and l, with k not equal to l. N is the population size. The value `eps` is used to control `pik` (pik>eps & pik < 1-eps).

```

varest *Variance estimation using the Deville's method*

Description

Computes the variance estimation of an estimator of the population total using the Deville's method.

Usage

```
varest(Ys,Xs=NULL,pik,w=NULL)
```

Arguments

Ys	vector of the variable of interest; its length is equal to n, the sample size.
Xs	matrix of the auxiliary variables; for the calibration estimator, this is the matrix of the sample calibration variables.
pik	vector of the first-order inclusion probabilities; its length is equal to n, the sample size.
w	vector of the calibrated weights (for the calibration estimator); its length is equal to n, the sample size.

Details

The function implements the following estimator:

$$\widehat{Var}(\widehat{Ys}) = \frac{1}{1-\sum_{k\in s} a_k^2} \sum_{k\in s}(1-\pi_k)\left(\frac{y_k}{\pi_k} - \frac{\sum_{l\in s}(1-\pi_l)y_l/\pi_l}{\sum_{l\in s}(1-\pi_l)}\right)$$

where $a_k = (1-\pi_k)/\sum_{l\in s}(1-\pi_l)$.

# vignette("calibration", package="sampling")
```

---

varHT *Variance estimators of the Horvitz-Thompson estimator*

Description

Computes variance estimators of the Horvitz-Thompson estimator of the population total.

Usage

```
varHT(y,pikl,method)
```

Arguments

y	vector of the variable of interest; its length is equal to n, the sample size.
pikl	matrix of joint inclusion probabilities; its dimension is nxn.
method	if 1, an unbiased variance estimator is computed; if 2, the Sen-Yates-Grundy variance estimator for fixed sample size is computed; be default, the method is 1.

Details

If method is 1, the following estimator is implemented

$$\widehat{Var}(\widehat{Y}_{HT})_1 = \sum_{k\in s}\sum_{\ell\in s}\frac{y_k y_\ell}{\pi_{k\ell}\pi_k\pi_\ell}(\pi_{k\ell}-\pi_k\pi_\ell)$$

If method is 2, the following estimator is implemented

$$\widehat{Var}(\widehat{Y}_{HT})_2 = \frac{1}{2}\sum_{k\in s}\sum_{\ell\in s}\left(\frac{y_k}{\pi_k}-\frac{y_\ell}{\pi_\ell}\right)^2\frac{\pi_k\pi_\ell-\pi_{k\ell}}{\pi_{k\ell}}$$

vartaylor_ratio *Taylor-series linearization variance estimation of a ratio*

Description

Computes the Taylor-series linearization variance estimation of the ratio

$$\frac{\widehat{Y}_s}{\widehat{X}_s}.$$

The estimators in the ratio are Horvitz-Thompson type estimators.

Usage

```
vartaylor_ratio(Ys,Xs,pikls)
```

Arguments

Ys	vector of the first observed variable; its length is equal to n, the sample size.
Xs	vector of the second observed variable; its length is equal to n, the sample size.
pikls	matrix of joint inclusion probabilities of the sample units; its dimension is nxn.

Details

The function implements the following estimator:

$$\widehat{Var}(\frac{\widehat{Ys}}{\widehat{Xs}}) = \sum_{i \in s} \sum_{j \in s} \frac{\pi_{ij} - \pi_i \pi_j}{\pi_{ij}} \frac{\widehat{z}_i \widehat{z}_j}{\pi_i \pi_j}$$

where $\widehat{z}_i = (Ys_i - \widehat{r} Xs_i)/\widehat{X}_s, \widehat{r} = \widehat{Y}_s/\widehat{X}_s, \widehat{Y}_s = \sum_{i \in s} Ys_i/\pi_i, \widehat{X}_s = \sum_{i \in s} Xs_i/\pi_i$.

# ratio estimator and its estimated variance
vartaylor_ratio(Ys,Xs,pikls)
```

---

writesample *All possible samples of fixed size*

Description

Gives a matrix whose rows are the vectors (with 0 and 1; 1 - a unit is selected, 0 - otherwise) of all samples of fixed size.

Usage

```
writesample(n,N)
```

Arguments

n	sample size.
N	population size.
