

# Package ‘splitstackshape’

July 23, 2025

**Type** Package

**Title** Stack and Reshape Datasets After Splitting Concatenated Values

**Version** 1.4.8

**Date** 2019-04-21

**Author** Ananda Mahto

**Maintainer** Ananda Mahto <mrwab@gmail.com>

**Description** Online data collection tools like Google Forms often export multiple-response questions with data concatenated in cells. The `concat.split` (`cSplit`) family of functions splits such data into separate cells. The package also includes functions to stack groups of columns and to reshape wide data, even when the data are “unbalanced”---something which `reshape` (from base R) does not handle, and which `melt` and `dcast` from `reshape2` do not easily handle.

**License** GPL-3

**LazyData** TRUE

**LazyLoad** yes

**Depends** R (>= 2.10)

**Imports** data.table (>= 1.9.4)

**URL** <http://github.com/mrdwab/splitstackshape>

**BugReports** <http://github.com/mrdwab/splitstackshape/issues>

**RoxygenNote** 6.1.1

**Suggests** covr, testthat

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2019-04-21 20:00:03 UTC

Description

Stack and Reshape Datasets After Splitting Concatenated Values

Details

Package: splitstackshape  
Type: Package  
Version: 1.4.8  
Date: 2019-04-21  
License: GPL-3

Online data collection tools like Google Forms often export multiple-response questions with data concatenated in cells. The `concat.split()` family of functions splits such data into separate cells.

The package also includes functions to *stack* groups of columns and to *reshape* wide data, even when the data are "unbalanced"—something which `stats::reshape()` does not handle, and which `reshape2::melt()` and `reshape2::dcast()` from *reshape2* do not easily handle.

Maintainer: Ananda Mahto [mrdwab@gmail.com](mailto:mrdwab@gmail.com)

## Examples

```
## concat.split
head(cSplit(concat.test, "Likes", drop = TRUE))

## Reshape
set.seed(1)
mydf <- data.frame(id_1 = 1:6, id_2 = c("A", "B"), varA.1 = sample(letters, 6),
                  varA.2 = sample(letters, 6), varA.3 = sample(letters, 6),
                  varB.2 = sample(10, 6), varB.3 = sample(10, 6),
                  varC.3 = rnorm(6))

mydf
Reshape(mydf, id.vars = c("id_1", "id_2"),
        var.stubs = c("varA", "varB", "varC"))

## Stacked
Stacked(data = mydf, id.vars = c("id_1", "id_2"),
        var.stubs = c("varA", "varB", "varC"),
        sep = ".")

## Not run:
## Processing times
set.seed(1)
Nrow <- 1000000
Ncol <- 10
mybigdf <- cbind(id = 1:Nrow, as.data.frame(matrix(rnorm(Nrow*Ncol),
                                                    nrow=Nrow)))

head(mybigdf)
dim(mybigdf)
tail(mybigdf)
A <- names(mybigdf)
names(mybigdf) <- c("id", paste("varA", 1:3, sep = "_"),
                  paste("varB", 1:4, sep = "_"),
                  paste("varC", 1:3, sep = "_"))

system.time({
  O1 <- Reshape(mybigdf, id.vars = "id",
               var.stubs = c("varA", "varB", "varC"), sep = "_")
  O1 <- O1[order(O1$id, O1$time), ]
})
system.time({
  O2 <- merged.stack(mybigdf, id.vars="id",
                    var.stubs=c("varA", "varB", "varC"), sep = "_")
})
system.time({
```

```

03 <- Stacked(mybigdf, id.vars="id",
var.stubs=c("varA", "varB", "varC"), sep = "_")
})
DT <- data.table(mybigdf)
system.time({
  04 <- merged.stack(DT, id.vars="id",
var.stubs=c("varA", "varB", "varC"), sep = "_")
})

## End(Not run)

```

---

charMat

---

*Create a Binary Matrix from a List of Character Values*

---

## Description

Create a binary matrix from a list of character values

## Usage

```
charMat(listOfValues, fill = NA, mode = "binary")
```

## Arguments

|              |                                                    |
|--------------|----------------------------------------------------|
| listOfValues | A list of input values to be inserted in a matrix. |
| fill         | The initializing fill value for the empty matrix.  |
| mode         | Either "binary" or "value". Defaults to "binary".  |

## Details

This is primarily a helper function for the [concat.split\(\)](#) function when creating the "expanded" structure. The input is anticipated to be a list of values obtained using [base::strsplit\(\)](#).

## Value

A matrix.

## Author(s)

Ananda Mahto

## See Also

[base::strsplit\(\)](#), [numMat\(\)](#).

**Examples**

```

invec <- c("rock,electro","electro","rock,jazz")
A <- strsplit(invec, ",")
splitstackshape::charMat(A)
splitstackshape::charMat(A, 0)
splitstackshape::charMat(A, mode = "value")

```

concat.split

*Split Concatenated Cells in a Dataset***Description**

The `concat.split` function takes a column with multiple values, splits the values into a list or into separate columns, and returns a new `data.frame` or `data.table`.

**Usage**

```

concat.split(data, split.col, sep = ",", structure = "compact",
  mode = NULL, type = NULL, drop = FALSE, fixed = FALSE,
  fill = NA, ...)

```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | The source <code>data.frame</code> or <code>data.table</code> .                                                                                                                                                                                                                                                                                   |
| <code>split.col</code> | The variable that needs to be split; can be specified either by the column number or the variable name.                                                                                                                                                                                                                                           |
| <code>sep</code>       | The character separating each value (defaults to <code>","</code> ).                                                                                                                                                                                                                                                                              |
| <code>structure</code> | Can be either <code>"compact"</code> , <code>"expanded"</code> , or <code>list</code> . Defaults to <code>"compact"</code> . See Details.                                                                                                                                                                                                         |
| <code>mode</code>      | Can be either <code>"binary"</code> or <code>"value"</code> (where <code>"binary"</code> is default and it recodes values to 1 or NA, like Boolean data, but without assuming 0 when data is not available). This setting only applies when <code>structure = "expanded"</code> ; a warning message will be issued if used with other structures. |
| <code>type</code>      | Can be either <code>"numeric"</code> or <code>"character"</code> (where <code>"numeric"</code> is default). This setting only applies when <code>structure = "expanded"</code> ; a warning message will be issued if used with other structures.                                                                                                  |
| <code>drop</code>      | Logical (whether to remove the original variable from the output or not). Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                        |
| <code>fixed</code>     | Is the input for the <code>sep</code> value <i>fixed</i> , or a <i>regular expression</i> ? See Details.                                                                                                                                                                                                                                          |
| <code>fill</code>      | The "fill" value for missing values when <code>structure = "expanded"</code> . Defaults to NA.                                                                                                                                                                                                                                                    |
| <code>...</code>       | Additional arguments to <code>cSplit()</code> .                                                                                                                                                                                                                                                                                                   |

## Details

### *structure*

- "compact" creates as many columns as the maximum length of the resulting split. This is the most useful general-case application of this function.
- When the input is numeric, "expanded" creates as many columns as the maximum value of the input data. This is most useful when converting to mode = "binary".
- "list" creates a single new column that is structurally a list within a data.frame or data.table.

### *fixed*

- When structure = "expanded" or structure = "list", it is possible to supply a regular expression containing the characters to split on. For example, to split on " ", ";", or "|", you can set sep = " , | ; |\\| " or sep = "[ , ; | ]", and fixed = FALSE to split on any of those characters.

## Note

This is more of a "legacy" or "convenience" wrapper function encompassing the features available in the separated functions of `cSplit()`, `cSplit_l()`, and `cSplit_e()`.

## Author(s)

Ananda Mahto

## See Also

`cSplit()`, `cSplit_l()`, `cSplit_e()`

## Examples

```
## Load some data
temp <- head(concat.test)

# Split up the second column, selecting by column number
concat.split(temp, 2)

# ... or by name, and drop the offensive first column
concat.split(temp, "Likes", drop = TRUE)

# The "Hates" column uses a different separator
concat.split(temp, "Hates", sep = ";", drop = TRUE)

## Not run:
# You'll get a warning here, when trying to retain the original values
concat.split(temp, 2, mode = "value", drop = TRUE)

## End(Not run)

# Try again. Notice the differing number of resulting columns
```

```

concat.split(temp, 2, structure = "expanded",
mode = "value", type = "numeric", drop = TRUE)

# Let's try splitting some strings... Same syntax
concat.split(temp, 3, drop = TRUE)

# Strings can also be split to binary representations
concat.split(temp, 3, structure = "expanded",
type = "character", fill = 0, drop = TRUE)

# Split up the "Likes column" into a list variable; retain original column
head(concat.split(concat.test, 2, structure = "list", drop = FALSE))

# View the structure of the output to verify
# that the new column is a list; note the
# difference between "Likes" and "Likes_list".
str(concat.split(temp, 2, structure = "list", drop = FALSE))

```

---

concat.split.compact    *Split Concatenated Cells into a Condensed Format*

---

## Description

The default splitting method for `concat.split`. Formerly based on `read.concat()` but presently a simple wrapper around `cSplit()`.

## Usage

```
concat.split.compact(data, split.col, sep = ",", drop = FALSE,
  fixed = TRUE, ...)
```

## Arguments

|                        |                                                                                                                             |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | The input data.frame or data.table.                                                                                         |
| <code>split.col</code> | The column that need to be split.                                                                                           |
| <code>sep</code>       | The character separating each value.                                                                                        |
| <code>drop</code>      | Logical. Should the original variable be dropped? Defaults to FALSE.                                                        |
| <code>fixed</code>     | Logical. Should the split character be treated as a fixed pattern (TRUE) or a regular expression (FALSE)? Defaults to TRUE. |
| <code>...</code>       | optional arguments to pass to <code>cSplit</code> .                                                                         |

## Value

A data.table.

**Note**

THIS FUNCTION IS DEPRECATED AND WILL BE REMOVED FROM LATER VERSIONS OF "SPLITSTACKSHAPE". It no longer does anything different from `cSplit()`. It is recommended that you transition your code to the `cSplit` function instead.

**Author(s)**

Ananda Mahto

**See Also**

`read.concat()`, `cSplit()`

**Examples**

```
## Not run:
temp <- head(concat.test)
concat.split.compact(temp, "Likes")
concat.split.compact(temp, 4, ";")

## Extra arguments to cSplit
concat.split.compact(temp, "Siblings", drop = TRUE, stripWhite = TRUE)

## End(Not run)
```

---

concat.split.expanded *Split Concatenated Values into their Corresponding Column Position*

---

**Description**

"Expand" concatenated numeric or character values to their relevant position in a `data.frame` or `data.table` or create a binary representation of such data.

**Usage**

```
cSplit_e(data, split.col, sep = ",", mode = NULL, type = "numeric",
  drop = FALSE, fixed = TRUE, fill = NA)
```

**Arguments**

|                        |                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | The source <code>data.frame</code> or <code>data.table</code> .                                                                                                                  |
| <code>split.col</code> | The variable that needs to be split (either name or index position).                                                                                                             |
| <code>sep</code>       | The character separating each value. Can also be a regular expression.                                                                                                           |
| <code>mode</code>      | Can be either "binary" (where presence of a number in a given column is converted to "1") or "value" (where the value is retained and not recoded to "1"). Defaults to "binary". |

|       |                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type  | Can be either "numeric" (where the items being split are integers) or "character" (where the items being split are character strings). Defaults to "numeric". |
| drop  | Logical. Should the original variable be dropped? Defaults to FALSE.                                                                                          |
| fixed | Used for <code>base::strsplit()</code> for allowing regular expressions to be used.                                                                           |
| fill  | Desired "fill" value. Defaults to NA.                                                                                                                         |

**Value**

A `data.frame` or `data.table` depending on the source input.

**Author(s)**

Ananda Mahto

**See Also**

`cSplit()`, `cSplit_l()`, `numMat()`, `charMat()`

**Examples**

```
temp <- head(concat.test)
cSplit_e(temp, "Likes")
cSplit_e(temp, 4, ";", fill = 0)

## The old function name still works
concat.split.expanded(temp, "Likes")
concat.split.expanded(temp, 4, ";", fill = 0)
concat.split.expanded(temp, 4, ";", mode = "value", drop = TRUE)
concat.split.expanded(temp, "Siblings", type = "character", drop = TRUE)
```

|                   |                                                    |
|-------------------|----------------------------------------------------|
| concat.split.list | <i>Split Concatenated Cells into a List Format</i> |
|-------------------|----------------------------------------------------|

---

**Description**

Takes a column in a `data.frame` or `data.table` with multiple values, splits the values into a list, and returns a new `data.frame` or `data.table`.

**Usage**

```
cSplit_l(data, split.col, sep = ",", drop = FALSE, fixed = FALSE)
```

**Arguments**

|                        |                                                                                     |
|------------------------|-------------------------------------------------------------------------------------|
| <code>data</code>      | The source data.frame or data.table.                                                |
| <code>split.col</code> | The variable that needs to be split (either name or index position).                |
| <code>sep</code>       | The character separating each value. Can also be a regular expression.              |
| <code>drop</code>      | Logical. Should the original variable be dropped? Defaults to FALSE.                |
| <code>fixed</code>     | Used for <code>base::strsplit()</code> for allowing regular expressions to be used. |

**Value**

A data.frame or data.table with the concatenated column split and added as a list.

**Author(s)**

Ananda Mahto

**See Also**

`cSplit()`, `cSplit_e()`

**Examples**

```
temp <- head(concat.test)
str(cSplit_l(temp, "Likes"))
cSplit_l(temp, 4, ";")

## The old function name still works
str(concat.split.list(temp, "Likes"))
concat.split.list(temp, 4, ";")
concat.split.list(temp, 4, ";", drop = TRUE)
```

---

`concat.split.multiple` *Split Concatenated Cells and Optionally Reshape the Output*

---

**Description**

This is a wrapper for the `cSplit()` function to maintain backwards compatibility with earlier versions of the "splitstackshape" package. It allows the user to split multiple columns at once and optionally convert the results into a "long" format.

**Usage**

```
concat.split.multiple(data, split.cols, seps = ",", direction = "wide",
  ...)
```

**Arguments**

|            |                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------|
| data       | The source data.frame or data.table.                                                                                                 |
| split.cols | A vector of columns that need to be split.                                                                                           |
| seps       | A vector of the separator character used in each column. If all columns use the same character, you can enter that single character. |
| direction  | The desired form of the resulting data.frame or data.table, either "wide" or "long". Defaults to "wide".                             |
| ...        | Other arguments to <code>cSplit()</code> .                                                                                           |

**Value**

A data.table.

**Author(s)**

Ananda Mahto

**See Also**

`cSplit()`

**Examples**

```
## Not run:
temp <- head(concat.test)
concat.split.multiple(temp, split.cols = c("Likes", "Hates", "Siblings"),
  seps = c(" ", ";", ","))
concat.split.multiple(temp, split.cols = c("Likes", "Siblings"),
  seps = " ", direction = "long")

## End(Not run)
```

---

concat.test

---

*Example Dataset with Concatenated Cells*

---

**Description**

This is a sample dataset to demonstrate the different features of the `concat.split()` family of functions.

**Format**

A data.frame in which many columns contain concatenated cells.

---

cSplit

---

*Split Concatenated Values into Separate Values*

---

**Description**

The `cSplit` function is designed to quickly and conveniently split concatenated data into separate values.

**Usage**

```
cSplit(indt, splitCols, sep = ",", direction = "wide", fixed = TRUE,
       drop = TRUE, stripWhite = TRUE, makeEqual = NULL,
       type.convert = TRUE)
```

**Arguments**

|                           |                                                                                                                                                                                                                                |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>indt</code>         | The input data.frame or data.table.                                                                                                                                                                                            |
| <code>splitCols</code>    | The column or columns that need to be split.                                                                                                                                                                                   |
| <code>sep</code>          | The values that serve as a delimiter <i>within</i> each column. This can be a single value if all columns have the same delimiter, or a vector of values <i>in the same order as the delimiters in each of the splitCols</i> . |
| <code>direction</code>    | The desired direction of the results, either "wide" or "long".                                                                                                                                                                 |
| <code>fixed</code>        | Logical. Should the split character be treated as a fixed pattern (TRUE) or a regular expression (FALSE)? Defaults to TRUE.                                                                                                    |
| <code>drop</code>         | Logical. Should the original concatenated column be dropped? Defaults to TRUE.                                                                                                                                                 |
| <code>stripWhite</code>   | Logical. If there is whitespace around the delimiter in the concatenated columns, should it be stripped prior to splitting? Defaults to TRUE.                                                                                  |
| <code>makeEqual</code>    | Logical. Should all groups be made to be the same length? Defaults to FALSE.                                                                                                                                                   |
| <code>type.convert</code> | Logical. Should <code>utils::type.convert()</code> be used to convert the result of each column? This would add a little to the execution time.                                                                                |

**Value**

A data.table with the values split into new columns or rows.

**Note**

The `cSplit` function replaces most of the earlier `concat.split*` functions. The earlier functions remain for compatibility purposes, but now they are essentially wrappers for the `cSplit` function.

**Author(s)**

Ananda Mahto

**See Also**[concat.split\(\)](#)**Examples**

```
## Sample data
temp <- head(concat.test)

## Split the "Likes" column
cSplit(temp, "Likes")

## Split the "Likes" and "Hates" columns --
## they have different delimiters...
cSplit(temp, c("Likes", "Hates"), c(",", ";"))

## Split "Siblings" into a long form...
cSplit(temp, "Siblings", ",", direction = "long")

## Split "Siblings" into a long form, not removing whitespace
cSplit(temp, "Siblings", ",", direction = "long", stripWhite = FALSE)

## Split a vector
y <- c("a_b_c", "a_b", "c_a_b")
cSplit(data.frame(y), "y", "_")
```

expandRows

*Expand the Rows of a Dataset***Description**

Expands (replicates) the rows of a `data.frame` or `data.table`, either by a fixed number, a specified vector, or a value contained in one of the columns in the source `data.frame` or `data.table`.

**Usage**

```
expandRows(dataset, count, count.is.col = TRUE, drop = TRUE)
```

**Arguments**

|                           |                                                                                                                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dataset</code>      | The input <code>data.frame</code> or <code>data.table</code> .                                                                                                                                    |
| <code>count</code>        | The numeric vector of counts OR the column from the dataset that contains the count data. If <code>count</code> is a single digit, it is assumed that all rows should be repeated by this amount. |
| <code>count.is.col</code> | Logical. Is the count value a column from the input dataset? Defaults to <code>TRUE</code> .                                                                                                      |
| <code>drop</code>         | Logical. If <code>count.is.col = TRUE</code> , should the "count" column be dropped from the result? Defaults to <code>TRUE</code> .                                                              |

**Value**

A `data.frame` or `data.table`, depending on the input.

**Author(s)**

Ananda Mahto

**References**

<http://stackoverflow.com/a/19519828/1270695>

**Examples**

```
mydf <- data.frame(x = c("a", "b", "q"),
                  y = c("c", "d", "r"),
                  count = c(2, 5, 3))
library(data.table)
DT <- as.data.table(mydf)
mydf
expandRows(mydf, "count")
expandRows(DT, "count", drop = FALSE)
expandRows(mydf, count = 3) ## This takes values from the third column!
expandRows(mydf, count = 3, count.is.col = FALSE)
expandRows(mydf, count = c(1, 5, 9), count.is.col = FALSE)
expandRows(DT, count = c(1, 5, 9), count.is.col = FALSE)
```

---

FacsToChars

*Convert All Factor Columns to Character Columns*

---

**Description**

Sometimes, we forget to use the `stringsAsFactors` argument when using `utils::read.table()` and related functions. By default, R converts character columns to factors. Instead of re-reading the data, the `FacsToChars` function will identify which columns are currently factors, and convert them all to characters.

**Usage**

```
FacsToChars(mydf)
```

**Arguments**

`mydf`                      The name of your `data.frame`

**Author(s)**

Ananda Mahto

**See Also**

```
utils::read.table()
```

**Examples**

```
## Some example data
dat <- data.frame(title = c("title1", "title2", "title3"),
                  author = c("author1", "author2", "author3"),
                  customerID = c(1, 2, 1))

str(dat) # current structure
dat2 <- splitstackshape::FacsToChars(dat)
str(dat2) # Your new object
str(dat)  # Original object is unaffected
```

---

getanID

*Add an "id" Variable to a Dataset*

---

**Description**

Many functions will not work properly if there are duplicated ID variables in a dataset. This function is a convenience function for .N from the "data.table" package to create an .id variable that when used in conjunction with the existing ID variables, should be unique.

**Usage**

```
getanID(data, id.vars = NULL)
```

**Arguments**

|         |                                                                                                                                              |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------|
| data    | The input data.frame or data.table.                                                                                                          |
| id.vars | The variables that should be treated as ID variables. Defaults to NULL, at which point all variables are used to create the new ID variable. |

**Value**

The input dataset (as a data.table) if ID variables are unique, or the input dataset with a new column named .id.

**Author(s)**

Ananda Mahto

**Examples**

```
mydf <- data.frame(IDA = c("a", "a", "a", "b", "b"),
                   IDB = c(1, 1, 1, 1, 1), values = 1:5)
mydf
getanID(mydf, c("IDA", "IDB"))

mydf <- data.frame(IDA = c("a", "a", "a", "b", "b"),
                   IDB = c(1, 2, 1, 1, 2), values = 1:5)
mydf
getanID(mydf, 1:2)
```

listCol\_1

*Unlist a Column Stored as a List***Description**

Unlists a column stored as a list into a long form.

**Usage**

```
listCol_1(inDT, listcol, drop = TRUE)
```

**Arguments**

|         |                                                                   |
|---------|-------------------------------------------------------------------|
| inDT    | The input dataset.                                                |
| listcol | The name of the column stored as a list.                          |
| drop    | Logical. Should the original column be dropped? Defaults to TRUE. |

**Value**

A data.table.

**Author(s)**

Ananda Mahto

**See Also**

[listCol\\_w](#) to flatten a list column into a "wide" format.

**Examples**

```
dat <- data.frame(A = 1:3, B = I(list(c(1, 2), c(1, 3, 5), c(4))))
listCol_1(dat, "B")
```

---

|           |                                          |
|-----------|------------------------------------------|
| listCol_w | <i>Flatten a Column Stored as a List</i> |
|-----------|------------------------------------------|

---

## Description

Flattens a column stored as a list into a wide form.

## Usage

```
listCol_w(inDT, listcol, drop = TRUE, fill = NA_character_)
```

## Arguments

|         |                                                                   |
|---------|-------------------------------------------------------------------|
| inDT    | The input dataset.                                                |
| listcol | The name of the column stored as a list.                          |
| drop    | Logical. Should the original column be dropped? Defaults to TRUE. |
| fill    | The desired fill value. Defaults to NA_character_.                |

## Value

A data.table.

## Author(s)

Ananda Mahto

## See Also

[listCol\\_l](#) to unlist a list column into a "long" format.

## Examples

```
dat <- data.frame(A = 1:3, B = I(list(c(1, 2), c(1, 3, 5), c(4))))  
listCol_w(dat, "B")
```

merged.stack

*Take a List of Stacked data.tables and Merge Them***Description**

A wrapper around the [Stacked](#) function to [merge](#) the resulting list into a single data.table.

**Usage**

```
merged.stack(data, id.vars = NULL, var.stubs, sep, keep.all = TRUE,
  ...)
```

**Arguments**

|           |                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data      | The input data.frame.                                                                                                                                                                    |
| id.vars   | The columns to be used as "ID" variables. Defaults to NULL, at which point, all names which are not identified as variable groups are used as the identifiers.                           |
| var.stubs | The prefixes of the variable groups.                                                                                                                                                     |
| sep       | The character that separates the "variable name" from the "times" in the source data.frame. Alternatively, can be set to "var.stubs" (in quotes) if you do not have a value for sep.     |
| keep.all  | Logical. Should all the variables in the source data.frame be kept (keep.all = TRUE) or only those which comprise the id.vars and split data from the var.stubs (keep.all = FALSE).      |
| ...       | Other arguments to be passed on to <a href="#">Stacked</a> (for example, keep.rownames to retain the rownames of the input dataset, or atStart, in case sep = "var.stubs" is specified). |

**Value**

A merged data.table.

**Note**

The keyed argument to [Stacked](#) has been hard-coded to TRUE to make merge work.

**Author(s)**

Ananda Mahto

**See Also**

[Stacked](#), [Reshape](#)

**Examples**

```

set.seed(1)
mydf <- data.frame(id_1 = 1:6, id_2 = c("A", "B"),
                   varA.1 = sample(letters, 6),
                   varA.2 = sample(letters, 6),
                   varA.3 = sample(letters, 6),
                   varB.2 = sample(10, 6),
                   varB.3 = sample(10, 6),
                   varC.3 = rnorm(6))

mydf
merged.stack(mydf, var.stubs = c("varA", "varB", "varC"), sep = ".")

```

Names

*Dataset Names as a Character Vector, Always***Description**

A convenience function using either character vectors or numeric vectors to specify a subset of names of a `data.frame`.

**Usage**

```
Names(data, invec)
```

**Arguments**

|                    |                                     |
|--------------------|-------------------------------------|
| <code>data</code>  | The input <code>data.frame</code> . |
| <code>invec</code> | The names you want.                 |

**Value**

A character vector of the desired names.

**Author(s)**

Ananda Mahto

**Examples**

```

mydf <- data.frame(a = 1:2, b = 3:4, c = 5:6)
splitstackshape::Names(mydf, c("a", "c"))
splitstackshape::Names(mydf, c(1, 3))

```

NoSep

*Split Basic Alphanumeric Strings Which Have No Separators*

---

**Description**

Used to split strings like "Abc8" into "Abc" and "8".

**Usage**

```
NoSep(data, charfirst = TRUE)
```

**Arguments**

|           |                                                                                      |
|-----------|--------------------------------------------------------------------------------------|
| data      | The vector of strings to be split.                                                   |
| charfirst | Is the string constructed with characters at the start or numbers? Defaults to TRUE. |

**Value**

A data.frame with two columns, .var and .time\_1.

**Note**

This is a helper function for the [Stacked\(\)](#) and [Reshape\(\)](#) functions.

**Author(s)**

Ananda Mahto

**See Also**

[base::strsplit\(\)](#)

**Examples**

```
x <- paste0("Var", LETTERS[1:3], 1:3)
splitstackshape::NoSep(x)

y <- paste0(1:3, "Var", LETTERS[1:3])
splitstackshape::NoSep(y, charfirst = FALSE)
```

numMat

*Create a Numeric Matrix from a List of Values***Description**

Create a numeric matrix from a list of values

**Usage**

```
numMat(listOfValues, fill = NA, mode = "binary")
```

**Arguments**

|              |                                                    |
|--------------|----------------------------------------------------|
| listOfValues | A list of input values to be inserted in a matrix. |
| fill         | The initializing fill value for the empty matrix.  |
| mode         | Either "binary" or "value". Defaults to "binary".  |

**Details**

This is primarily a helper function for the [concat.split\(\)](#) function when creating the "expanded" structure. The input is anticipated to be a list of values obtained using [base::strsplit\(\)](#).

**Value**

A matrix.

**Author(s)**

Ananda Mahto

**See Also**

[base::strsplit\(\)](#), [charMat\(\)](#).

**Examples**

```
invec <- c("1,2,4,5,6", "1,2,4,5,6", "1,2,4,5,6",
           "1,2,4,5,6", "-1,1,2,5,6", "1,2,5,6")
A <- strsplit(invec, ",")
splitstackshape::numMat(A)
splitstackshape::numMat(A, fill = 0)
splitstackshape::numMat(A, mode = "value")
```

---

othernames

*Extract All Names From a Dataset Other Than the Ones Listed*

---

### Description

A convenience function for `setdiff(names(data), -some_vector_of_names-)`.

### Usage

```
othernames(data, toremove)
```

### Arguments

|                       |                                     |
|-----------------------|-------------------------------------|
| <code>data</code>     | The input <code>data.frame</code> . |
| <code>toremove</code> | The names you want to exclude.      |

### Value

A character vector of the remaining names.

### Author(s)

Ananda Mahto

### See Also

[base::setdiff\(\)](#)

### Examples

```
mydf <- data.frame(a = 1:2, b = 3:4, c = 5:6)
splitstackshape::othernames(mydf, "a")
```

---

read.concat

*Read Concatenated Character Vectors Into a data.frame*

---

### Description

Originally a helper function for the `concat.split.compact()` function. This function has now been effectively replaced by `cSplit()`.

### Usage

```
read.concat(data, col.prefix, sep, ...)
```

**Arguments**

|                         |                                                                    |
|-------------------------|--------------------------------------------------------------------|
| <code>data</code>       | The input data.                                                    |
| <code>col.prefix</code> | The desired column prefix for the output <code>data.frame</code> . |
| <code>sep</code>        | The character that acts as a delimiter.                            |
| <code>...</code>        | Other arguments to pass to <code>utils::read.table()</code> .      |

**Value**

A `data.frame`.

**Author(s)**

Ananda Mahto

**See Also**

`utils::read.table()`

**Examples**

```
vec <- c("a,b", "c,d,e", "f, g", "h, i, j,k")
splitstackshape::read.concat(vec, "var", ",")

## More than 5 lines the same
## `read.table` would fail with this
vec <- c("12,51,34,17", "84,28,17,10", "11,43,28,15",
"80,26,17,91", "10,41,25,13", "97,35,23,12,13")
splitstackshape::read.concat(vec, "var", ",")
```

---

Reshape

---

*Reshape Wide Data Into a Semi-long Form*

---

**Description**

The `stats::reshape()` function in base R is very handy when you want a semi-long (or semi-wide) `data.frame`. However, base R's reshape has problems is with "unbalanced" panel data, for instance data where one variable was measured at three points in time, and another only twice.

**Usage**

```
Reshape(data, id.vars = NULL, var.stubs, sep = ".", rm.rownames, ...)
```

**Arguments**

|                          |                                                                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>        | The source <code>data.frame</code> .                                                                                                                                               |
| <code>id.vars</code>     | The variables that serve as unique identifiers. Defaults to <code>NULL</code> , at which point, all names which are not identified as variable groups are used as the identifiers. |
| <code>var.stubs</code>   | The prefixes of the variable groups.                                                                                                                                               |
| <code>sep</code>         | The character that separates the "variable name" from the "times" in the wide <code>data.frame</code> .                                                                            |
| <code>rm.rownames</code> | Ignored as <code>data.tables</code> do not have rownames anyway.                                                                                                                   |
| <code>...</code>         | Further arguments to <code>NoSep()</code> in case the separator is of a different form.                                                                                            |

**Details**

This function was written to overcome that limitation of dealing with unbalanced data, but is also appropriate for basic wide-to-long reshaping tasks.

Related functions like `utils::stack()` in base R and `reshape2::melt()` in "reshape2" are also very handy when you want a "long" reshaping of data, but they result in a very long structuring of your data, not the "semi-wide" format that `reshape` produces. `data.table::melt()` can produce output like `reshape`, but it also expects an equal number of measurements for each variable.

**Value**

A "long" `data.table` of the reshaped data that retains the attributes added by base R's `reshape` function.

**Author(s)**

Ananda Mahto

**See Also**

`Stacked()`, `utils::stack()`, `stats::reshape()`, `reshape2::melt()`, `data.table::melt()`

**Examples**

```
set.seed(1)
mydf <- data.frame(id_1 = 1:6, id_2 = c("A", "B"), varA.1 = sample(letters, 6),
                  varA.2 = sample(letters, 6), varA.3 = sample(letters, 6),
                  varB.2 = sample(10, 6), varB.3 = sample(10, 6),
                  varC.3 = rnorm(6))

mydf

## Note that these data are unbalanced
## reshape() will not work
## Not run:
reshape(mydf, direction = "long", idvar=1:2, varying=3:ncol(mydf))

## End(Not run)
```

```
## The Reshape() function can handle such scenarios

Reshape(mydf, id.vars = c("id_1", "id_2"),
        var.stubs = c("varA", "varB", "varC"))
```

---

Stacked

---

*Stack Columns from a Wide Form to a Long Form*

---

**Description**

A function to conveniently stack groups of wide columns into a long form which can then be [merged](#) together.

**Usage**

```
Stacked(data, id.vars = NULL, var.stubs, sep, keep.all = TRUE,
        keyed = TRUE, keep.rownames = FALSE, ...)
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>          | The source <code>data.frame</code> .                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>id.vars</code>       | The variables that serve as unique identifiers. Defaults to <code>NULL</code> , at which point, all names which are not identified as variable groups are used as the identifiers.                                                                                                                                                                                                                                                                      |
| <code>var.stubs</code>     | The prefixes of the variable groups.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>sep</code>           | The character that separates the "variable name" from the "times" in the wide <code>data.frame</code> . Alternatively, can be set to <code>"var.stubs"</code> (in quotes) if you do not have a value for <code>sep</code> .                                                                                                                                                                                                                             |
| <code>keep.all</code>      | Logical. Should all the variables from the source <code>data.frame</code> be kept ( <code>keep.all = TRUE</code> ) or should the resulting <a href="#">data.table</a> comprise only columns for the <code>id.vars</code> , <code>var.stubs</code> , and "times" ( <code>keep.all = FALSE</code> ). Other variables are <i>recycled</i> to appropriate length. For this to work, both <code>id.vars</code> and <code>var.stubs</code> must be specified. |
| <code>keyed</code>         | Logical. Should the <code>Stacked</code> function automatically set the key for the resulting <code>data.tables</code> . If <code>TRUE</code> (default) the key is set to the <code>id.vars</code> and the "time" variables that are created by <code>Stacked</code> .                                                                                                                                                                                  |
| <code>keep.rownames</code> | Logical. Should rownames be kept when converting the input to a <code>data.table</code> ? Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                              |
| <code>...</code>           | Other arguments to be passed on when <code>sep = "var.stubs"</code> (specifically, <code>atStart</code> : A logical argument to indicate whether the stubs come at the start or at the end of the variable names).                                                                                                                                                                                                                                      |

**Value**

A list of `data.tables` with one `data.table` for each "var.stub". The [key](#) is set to the `id.vars` and `.time_# vars`.

**Note**

This is the function internally called by `merged.stack`.

**Author(s)**

Ananda Mahto

**See Also**

`stack`, `melt` from "reshape2".

**Examples**

```
set.seed(1)
mydf <- data.frame(id_1 = 1:6, id_2 = c("A", "B"),

```

---

stratified

---

*Take a Stratified Sample From a Dataset*

---

**Description**

The `stratified` function samples from a `data.table` in which one or more columns can be used as a "stratification" or "grouping" variable. The result is a new `data.table` with the specified number of samples from each group.

**Usage**

```
stratified(indt, group, size, select = NULL, replace = FALSE,
  keep.rownames = FALSE, bothSets = FALSE, ...)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>indt</code>  | The input <code>data.table</code> .                                                                                                                                                                                                                                                                                                                                                   |
| <code>group</code> | The column or columns that should be used to create the groups. Can be a character vector of column names (recommended) or a numeric vector of column positions. Generally, if you are using more than one variable to create your "strata", you should list them in the order of <i>slowest</i> varying to <i>quickest</i> varying. This can be a vector of names or column indexes. |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| size          | <p>The desired sample size.</p> <ul style="list-style-type: none"> <li>• If size is a value between 0 and 1 expressed as a decimal, size is set to be proportional to the number of observations per group.</li> <li>• If size is a single positive integer, it will be assumed that you want the same number of samples from each group.</li> <li>• If size is a named vector, the function will check to see whether the length of the vector matches the number of groups and that the names match the group names.</li> </ul> |
| select        | A named list containing levels from the "group" variables in which you are interested. The list names must be present as variable names for the input dataset.                                                                                                                                                                                                                                                                                                                                                                    |
| replace       | Logical. Should sampling be with replacement? Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| keep.rownames | Logical. If the input is a data.frame with rownames, as.data.table would normally drop the rownames. If TRUE, the rownames would be retained in a column named rn. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                             |
| bothSets      | Logical. Should both the sampled and non-sampled sets be returned as a list? Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ...           | Optional arguments to <code>base::sample()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Value**

If bothSets = TRUE, a list of two data.tables; otherwise, a data.table.

**Note**

*Slightly different sizes than requested:* Because of how computers deal with floating-point arithmetic, and because R uses a "round to even" approach, the size per strata that results when specifying a proportionate sample may be one sample higher or lower per strata than you might have expected.

**Author(s)**

Ananda Mahto

**See Also**

`sampling::strata()` from the "strata" package; `dplyr::sample_n()` and `dplyr::sample_frac()` from "dplyr".

**Examples**

```
# Generate a sample data.frame to play with
set.seed(1)
DF <- data.frame(
  ID = 1:100,
  A = sample(c("AA", "BB", "CC", "DD", "EE"), 100, replace = TRUE),
  B = rnorm(100), C = abs(round(rnorm(100), digits=1)),
  D = sample(c("CA", "NY", "TX"), 100, replace = TRUE),
  E = sample(c("M", "F"), 100, replace = TRUE))
```

```

# Take a 10% sample from all -A- groups in DF
stratified(DF, "A", .1)

# Take a 10% sample from only "AA" and "BB" groups from -A- in DF
stratified(DF, "A", .1, select = list(A = c("AA", "BB")))

# Take 5 samples from all -D- groups in DF, specified by column number
stratified(DF, group = 5, size = 5)

# Use a two-column strata: -E- and -D-
stratified(DF, c("E", "D"), size = .15)

# Use a two-column strata (-E- and -D-) but only use cases where -E- == "M"
stratified(DF, c("E", "D"), .15, select = list(E = "M"))

## As above, but where -E- == "M" and -D- == "CA" or "TX"
stratified(DF, c("E", "D"), .15, select = list(E = "M", D = c("CA", "TX")))

# Use a three-column strata: -E-, -D-, and -A-
stratified(DF, c("E", "D", "A"), size = 2)

## Not run:
# The following will produce errors
stratified(DF, "D", c(5, 3))
stratified(DF, "D", c(5, 3, 2))

## End(Not run)

# Sizes using a named vector
stratified(DF, "D", c(CA = 5, NY = 3, TX = 2))

# Works with multiple groups as well
stratified(DF, c("D", "E"),
  c("NY F" = 2, "NY M" = 3, "TX F" = 1, "TX M" = 1,
    "CA F" = 5, "CA M" = 1))
