Title High-Level Interface for Survival Analysis and Associated Plots

Version 0.4.0

Author Marcel Wiesweg [aut, cre]

Maintainer Marcel Wiesweg <marcel.wiesweg@uk-essen.de>

Description A high-level interface to perform survival analysis,

including Kaplan-Meier analysis and log-rank tests and Cox regression.

Aims at providing a clear and elegant syntax, support for use in a pipeline, structured output and plotting.

Builds upon the 'survminer' package for Kaplan-Meier plots and provides a customizable implementation for forest plots.

Description

Performs Cox regression on right-censored data using a multiple covariates.

Usage

```
analyse_multivariate(
  data,
  time_status,
  covariates,
  interaction_covariates = NULL,
  strata = NULL,
  covariate_name_dict = NULL,
  covariate_label_dict = NULL,
 reference_level_dict = NULL,
  sort_frame_by = vars(HR)
)
```

analyse_multivariate 3

```
analyze_multivariate(
  data,
  time_status,
  covariates,
  interaction_covariates = NULL,
  strata = NULL,
  covariate_name_dict = NULL,
  covariate_label_dict = NULL,
  reference_level_dict = NULL,
  sort_frame_by = vars(HR)
)
```

Arguments

data

A data frame containing the time/status information and, if used, the covariate.

time_status

A vector of length 2 giving the time and status fields. It is recommended to use vars() and symbolic column names or code that is tidily-evaluated on data. You can also pass a character vector with the column names or a numeric vector with column indices.

covariates

The covariates. Pass symbolic columns names or code that is tidily-evaluated on data. Column names or column indices are also possible. In any case, factors with appropriate labels will be generated which in all printouts. You can use covariate_name_dict and covariate_label_dict to rename these factors and their levels.

interaction_covariates

Interactions (optional). Same format as covariates. Covariates to include together with their interaction (*, not + in the formula)

strata

Strata (optional). Same format as covariates. For each strata level (if multiple fields, unique combinations of levels) a separate baseline hazard is fit.

covariate name dict

A dictionary (named list or vector) of old->new covariate names

covariate_label_dict

A dictionary (named list or vector) of old->new covariate value level labels

reference_level_dict

For categorical variables, the Cox regression uses pseudo variables for each level relative to a reference category, resulting in n-1 variables for n levels of a categorical covariate. Hazard ratios will be relative to the reference level, which is defined as having hazard ratio 1.0. Per default, the reference level is the first factor level. You can specify a different level by passing a named vector: factor name -> value of reference level. Note that this is independent of covariate_label_dict, i.e. specify the factor level as it is in data#'

sort_frame_by

A vars() list of one or more symbolic column names. The result contains a data frame of the cox regression results (cox_as_data_frame). This frame contains the variables "Lower_CI", "HR", "Upper_CI", "Inv_Lower_CI", "Inv_HR", "Inv_Upper_CI", "p". You can specify by which variables the frame should be sorted. Default: Hazard Ratio.

4 analyse_survival

Details

This method builds upon the survival package and returns a comprehensive result object for survival analysis containing the coxph results. A format/print method is provided that prints the essential statistics.

Value

An object of class "SurvivalAnalysisResult" and "SurvivalAnalysisMultivariateResult". You can use this result as a black box for further functions in this package, format or print it, retrieve information as a data frame via multivariate_as_data_frame or access individual pieces via pluck_multivariate_analysis

See Also

```
forest_plot
```

Examples

analyse_survival

Univariate survival analysis

Description

Performs survival analysis on right-censored data using a single covariate, or no covariate.

Usage

```
analyse_survival(
  data,
  time_status,
  by,
  by_label_map = NULL,
  by_order_vector = NULL,
  cox_reference_level = NULL,
  p_adjust_method = "none",
  plot_args = list()
)
analyze_survival(
  data,
```

analyse_survival 5

```
time_status,
by,
by_label_map = NULL,
by_order_vector = NULL,
cox_reference_level = NULL,
p_adjust_method = "none",
plot_args = list()
)
```

Arguments

data

A data frame containing the time/status information and, if used, the covariate.

time status

A vector of length 2 giving the time and status fields. It is recommended to use vars() and symbolic column names or code that is tidily-evaluated on data. You can also pass a character vector with the column names or a numeric vector with column indices.

by

The term by which survival curves will be separated. Pass NULL or omit to generate a single curve and only descriptive statistics. Pass symbolic columns names or code that is tidily-evaluated on data to generate more than one curve, and the appropriate statistics to compare the curves. A column name or column index is also possible. In any case, the parameter will be used to create a factor with appropriate labels. This factor will appear in all printouts and plots. You can use by_label_map and by_order_vector to rename and reorder this factor.

by_label_map

A dictionary (named list or vector) of old->new labels of the factor created using by. The factor will be renamed accordingly, and also reordered by the order of the vector.

by_order_vector

A vector of the labels of the factor created using by, after renaming them based on by_label_map (so specify the "new" level). The factor will be ordered according to the order of this vector. It need not contain all elements, only those found will be reorder at the top.

cox_reference_level

The result will include a univariate Cox regression. Use this parameter to specify the level of the factor generated using by that you want to use a the reference level (Hazard ratios will be relative to the reference level, which is defined as having hazard ratio 1.0) Note that the given string applies after all renaming has been done, so specify the "new" level.

p_adjust_method

If there are more than two levels in the by factor, the result will include the return value of pairwise_survdiff, which performs p adjustment. You can specify the desired method here. Note that other p values are not corrected, this is beyond the scope of this method.

plot_args

Named list of arguments that will be stored for later use in plotting methods, such as kaplan_meier_plot. There they will take precedence over arguments given to that method. This is useful when plotting multiple results with a set of default arguments, of which some such as title or axis scale differ per-plot.

6 cox_as_data_frame

Details

This method builds upon the survival package and returns a comprehensive result object for survival analysis containing the survfit, survdiff and coxph results. A format/print method is provided that prints the essential statistics. Kaplan-Meier plots are readily generated using the kaplan_meier_plot or kaplan_meier_grid functions.

Value

An object of class "SurvivalAnalysisResult" and "SurvivalAnalysisUnivariateResult". You can use this result as a black box for further functions in this package, format or print it, retrieve information as a data frame via survival_data_frames or access individual pieces via pluck_survival_analysis

Examples

```
library(magrittr)
library(dplyr)
survival::aml %>%
 analyse_survival(vars(time, status), x) %>%
```

cox_as_data_frame

Turns a coxph result to a data frame

Description

Extracts useful information from a coxph/summary.coxph into a data frame which is ready for printing or further analysis

Usage

```
cox_as_data_frame(
  coxphsummary,
  unmangle_dict = NULL,
  factor_id_sep = ":",
  sort_by = NULL
)
```

Arguments

The summary.coxph or coxph result object coxphsummary

An unmangle dict of mangled column name -> readable column name (as creunmangle_dict

ated by analyse_multivariate)

factor_id_sep The frame contains one column "factor.id" which is a composite of covariate name and, if categorical, the factor level (one line for each factor level except

for the reference level)

sort_by

A vars() list of one or more symbolic column names. This frame contains the variables "Lower_CI", "HR", "Upper_CI", "Inv_Lower_CI", "Inv_HR", "Inv_Upper_CI", "p". You can choose to sort by any combination. Use desc() to sort a variable in descending order.

Value

A tibble.

forest_plot

Forest plots for survival analysis.

Description

Creates a forest plot from SurvivalAnalysisResult objects. Both univariate (analyse_survival) results, typically with use_one_hot=TRUE, and multivariate (analyse_multivariate) results are acceptable.

Usage

```
forest_plot(
  use_one_hot = FALSE,
  factor_labeller = identity,
  endpoint_labeller = identity,
  orderer = identity_order,
  categorizer = NULL,
  relative_widths = c(1, 1, 1),
  ggtheme = theme_bw(),
  labels_displayed = c("endpoint", "factor"),
  label_headers = c(endpoint = "Endpoint", factor = "Subgroup", n = "n"),
  values_displayed = c("HR", "CI", "p"),
  value_headers = c(HR = "HR", CI = "CI", p = "p", n = "n", subgroup_n = "n"),
 HRsprintfFormat = "%.2f",
  psprintfFormat = "%.3f",
  p_lessthan_cutoff = 0.001,
  log_scale = TRUE,
 HR_x_breaks = seq(0, 10),
 HR_x_limits = NULL,
  factor_id_sep = ":",
  na_rm = TRUE,
  title = NULL,
  title_relative_height = 0.1,
  title_label_args = list(),
  base\_papersize = dinA(4)
```

```
forest_plot.df(
  .df,
  factor_labeller = identity,
  endpoint_labeller = identity,
  orderer = identity_order,
  categorizer = NULL,
  relative_widths = c(1, 1, 1),
  ggtheme = theme_bw(),
  labels_displayed = c("endpoint", "factor"),
  label_headers = c(endpoint = "Endpoint", factor = "Subgroup", n = "n"),
  values_displayed = c("HR", "CI", "p"),
  value_headers = c(HR = "HR", CI = "CI", p = "p", n = "n", subgroup_n = "n"),
  HRsprintfFormat = "%.2f",
  psprintfFormat = "%.3f",
  p_lessthan_cutoff = 0.001,
  log_scale = TRUE,
 HR_x_breaks = seq(0, 10),
 HR_x_limits = NULL,
  factor_id_sep = ":",
  na_rm = TRUE,
  title = NULL,
  title_relative_height = 0.1,
  title_label_args = list(),
  base_papersize = dinA(4)
)
```

Arguments

. . .

The SurvivalAnalysisResult objects. You can also pass one list of such objects, or use explicit splicing (!!! operator). If not use_one_hot, also a list of coxph objects, or a mix is acceptable.

use_one_hot

If not use_one_hot (default), will take univariate or multivariate results and plot hazard ratios against the reference level (as provided to the analyse_survival or analyse_multivariate function, or, per default, the first factor level), resulting in k-1 values for k levels. If use_one_hot == TRUE, will only accept univariate results from analyse_survival and plot HRs of one factor level vs. remaining cohort, resulting in k values for k levels.

• A function which returns labels for the input: First argument, a vector of either (factor.ids) or (endpoints), resp. If the function takes ... or two arguments, as second argument a data frame with (at least) the columns survivalResult, endpoint, factor.id, factor.name, factor.value, HR, Lower_CI, Upper_CI, p, n, where survivalResult is the corresponding result object passed to forest_plot; Note the function must be vectorized, if you have a non-vectorized function taking single arguments, you may want to have a look at purrr::map_chr or purrr::pmap_chr.

• a dictionaryish list, looks up by (endpoints) or (factor.ids). The factor.id value: For continous factors, the factor name (column name in data frame); For categorical factors, factor name, factor_id_sep, and the factor level value. (note: If use_one_hot = FALSE, the HR is factor level value vs. cox reference given to survival_analysis; if use_one_hot = TRUE, the HR is the factor level value vs. remaining population)

orderer

A function which returns an integer ordering vector for the input:

- if the supplied function takes exactly one argument, a data frame with (at least) the columns survivalResult, endpoint, factor.id, factor.name, factor.value, HR, Lower_CI, Upper_CI, p, n, subgroup_n where survivalResult is the corresponding result object passed to forest_plot;
- or, if the function takes more than one argument, or its arguments include ..., the nine vectors (endpoint, factor.name, factor.value, HR, Lower_CI, Upper_CI, p, n, subgroup_n): a vector of endpoints (as given to Surv(endpoint, ...) in coxph), a vector of factors (as given to the right hand side of the coxph formula), and numeric vectors of the HR, lower CI, upper CI, p-value
- You can create a function from ordered vectors via orderer_function_from_sorted_vectors, or call order() with one or more of these vectors.
- Alternatively, you can provide a quosure of code, or a right-hand side formula; it will be executed such that the above nine vectors are available as symbols.

Example:

- orderer = quo(order(endpoint, HR))
- equivalent to orderer = ~order(endpoint, HR)
- equivalent to orderer = function(df) df %\$% order(endpoint, HR)
- equivalent to orderer = function(df) { order(df\$endpoint, df\$HR) }
- equivalent to orderer = function(endpoint, factor.name, factor.value, HR, ...) order(endpoint, HR)

categorizer

A function which returns one logical value if a breaking line should be inserted _above_ the input: Same semantics as for orderer. !Please note!: The order of the data is not yet ordered as per your orderer! If you do calculations depending on order, first order with your own orderer function. A proper implementation is easy using sequential_duplicates, for example categorizer=~! sequential_duplicates(endpoin ordering = order(endpoint, HR))

relative_widths

relation of the width of the plots, labels, plot, values. Default is 1:1:1.

ggtheme

ggplot2 theme to use

labels_displayed

Combination of "endpoint", "factor", "n", determining what is shown on the left-hand table and in which order.

label_headers

Named vector with name=<allowed values of labels_displayed>, value=<your heading>.

values_displayed

Combination of "HR", "CI", "p", "subgroup_n", determining what is shown on the right-hand table and in which order. Note: subgroup_n is only applicable if oneHot=TRUE.

value_headers Named vector with name=<allowed values of values_displayed>, value=<your heading>.

HRsprintfFormat, psprintfFormat

sprintf() format strings for hazard ratio and p value

p_lessthan_cutoff

The lower limit below which p value will be displayed as "less than". If p_lessthan_cutoff == 0.001, the a p value of 0.002 will be displayed as is, while 0.0005 will become "p < 0.001".

log_scale Plot on log scale, which is quite common and gives symmetric length for the CI bars. Note that HRs of 0 (did not converge) will not be plotted in this case.

HR_x_breaks Breaks of the x scale for plotting HR and CI

HR_x_limits Limits of the x scale for plotting HR and CI. Default (HR_x_lim = NULL) depends on log_scale and existing limits. Pass NA to use the existing minimum and maximum values without interference. Pass a vector of size 2 to specify

(min, max) manually

factor_id_sep Allows you to customize the separator of the factor id, the documentation of

factor_labeller.

na_rm Only used in the multivariate case (use_one_hot = FALSE). Should null coeffi-

cients (NA/0/Inf) be removed?

title, title_relative_height, title_label_args

A title on top of the plot, taking a fraction of title_relative_height of the returned plot. The title is drawn using draw_label; you can specify any arguments to this function by giving title_label_args Per default, font attributes are taken from the "title" entry from the given ggtheme, and the label is drawn centered as per

draw_label defaults.

base_papersize numeric vector of length 2, c(width, height), unit inches. forest_plot will store a

suggested "papersize" attribute in the return value, computed from base_papersize and the number of entries in the plot (in particular, the height will be adjusted)
The attribute is read by save_pdf. It will also store a "forestplot_entries" attribute

which you can use for your own calculations.

.df Data frame containing the columns survivalResult, endpoint, factor.id, factor.name, factor.value, HR, Lower_CI, Upper_CI, p, n, subgroup_n giv-

ing the information that is to be presented in the forest plot

Details

The plot has a left column containing the labels (covariate name, levels for categorical variables, optionally subgroup size), the actual line plot in the middle column, and a right column to display the hazard ratios and their confidence intervals. A rich set of parameters allows full customizability to create publication-ready plots.

Value

A ggplot2 plot object

forest_plot_grid 11

Functions

• forest_plot.df(): Creates a forest plot from the given data frame

See Also

```
forest_plot_grid
```

Examples

forest_plot_grid

Create a grid of forest plots

Description

Makes use of the stored layout information in a forest_plot plot to create grids of plots.

Usage

```
forest_plot_grid(
    ...,
    nrow = NULL,
    ncol = NULL,
    byrow = TRUE,
    plot_grid_args = list()
)
```

Arguments

... Pass individual plots returned by forest_plot, or lists of such plots (bare lists will

be spliced).

nrow, ncol Specify the grid (one is sufficient, uses auto layout if both are null) byrow If the plots are given in by-row, or by-column (byrow=FALSE) order

plot_grid_args Additional arguments to the plot_grid function which is used to create the

grid.

Value

Return value of plot_grid

format.SurvivalAnalysisMultivariateResult

Formats a SurvivalAnalysisMultivariateResult for printing

Description

Formats a SurvivalAnalysisMultivariateResult for printing

Usage

```
## S3 method for class 'SurvivalAnalysisMultivariateResult'
format(x, ..., p_precision = 3, hr_precision = 2, p_less_than_cutoff = 0.001)
```

Arguments

Value

A formatted string, ready for output with cat()

```
format.SurvivalAnalysisUnivariateResult
```

Formats a SurvivalAnalysisUnivariateResult for printing

Description

Formats a SurvivalAnalysisUnivariateResult for printing

Usage

```
## S3 method for class 'SurvivalAnalysisUnivariateResult'
format(
    x,
    ...,
    label = NULL,
    p_precision = 3,
    hr_precision = 2,
    p_less_than_cutoff = 0.001,
    time_precision = 1,
```

ggsurvplot_to_gtable 13

```
include_end_separator = FALSE,
  timespan_unit = c("days", "months", "years")
```

Arguments

Value

A formatted string, ready for output with cat()

ggsurvplot_to_gtable Build a gtable representation from a ggsurvplot object

Description

Build a gtable representation from a ggsurvplot object

Usage

```
ggsurvplot_to_gtable(
  ggsurv_obj,
  surv.plot.height = NULL,
  risk.table.height = NULL,
  ncensor.plot.height = NULL)
```

Arguments

```
ggsurv_obj The ggsurvplot object
surv.plot.height, risk.table.height, ncensor.plot.height
Layout parameters, see arrange_ggsurvplots
```

Value

A gtable object

14 identity_order

grid_layout

Grid layouting

Description

Creates a grid layout nrow x ncol for n items.

Usage

```
grid_layout(n, rows = NULL, cols = NULL)
```

Arguments

n Number of items in grid

rows, cols Pass one of rows or cols, or none, in which case auto layout is used.

Value

A numeric vector of length 2: rows, cols

Examples

```
grid_layout(24, cols=4)
grid_layout(24)
grid_layout(24, rows=2)
```

identity_order

Ordering function: identity order

Description

This can be used in a place where a function with a signature like order is required. It simply retains the original order.

Usage

```
identity\_order(x, ...)
```

Arguments

x a vector

... Effectively ignored

Value

An integer vector

```
in_one_kaplan_meier_plot
```

Display multiple survival curves within the same Kaplan Meier plot

Description

Utility method to tell kaplan_meier_plot to combine the given survival results within the same plot

Usage

```
in_one_kaplan_meier_plot(...)
```

Arguments

. . .

Named SurvivalAnalysisResult objects as returned by analyse_survival. Please note that the results need to come from the same data source and should only differ by the "by" parameter. The first given result acts as source for common attributes. Also takes one single named bare list.

Value

Internal object for use by kaplan_meier_plot or kaplan_meier_grid only

kaplan_meier_grid

A grid of kaplan meier plots

Description

A grid of kaplan meier plots

Usage

```
kaplan_meier_grid(
    ...,
    nrow = NULL,
    ncol = NULL,
    layout_matrix = NULL,
    byrow = TRUE,
    mapped_plot_args = list(),
    paperwidth = NULL,
    paperheight = NULL,
    size_per_plot = dinAWidth(5),
    title = NA,
    surv.plot.height = NULL,
```

16 kaplan_meier_grid

```
risk.table.height = NULL,
ncensor.plot.height = NULL,
p_lessthan_cutoff = 0.001
)
```

Arguments

. . .

One or many SurvivalAnalysisResult objects as returned by analyse_survival and arguments that will be passed to ggsurvplot. Bare lists will be spliced. If using lists, the same argument may be contained in multiple lists; in this case, the last occurrence is used, i.e. you can first pass a list with default arguments, and then override some of them. If you want to combine two curves in one plot (ggsurvplot_combine), wrap them in in_one_kaplan_meier_plot when passing as argument here. (otherwise you will get a list with separate plots for each) In addition to all arguments supported by ggsurvplot, these arguments and shortcuts can be used additionally:

- break.time.by: breakByYear, breakByHalfYear, breakByQuarterYear, breakByMonth (numeric value only in ggsurvplot)
- xscale: scaleByYear, scaleByMonth (numeric value only in ggsurvplot)
- hazard.ratio (logical): display hazard ratios in addition to p value, complementing pval=T
- xlab: {.OS,.PFS,.TTF,.DFS}.{years,months,days}
- table.layout: clean, displays risk table only with color code and number, no grid, axes or labels. (do not forget risk.table=TRUE to see something)
- papersize: numeric vector of length 2, c(width, height), unit inches. kaplan_meier_plot will store a "papersize" attribute with this value which is read by save_pdf
- ggplot.add: ggplot2 object to add to the ggplot plot part of the created KM plot. One common use case is manual specification of the line type, which is currently not possible with ggsurvplot. The passed object can be result of "+" operations will be added via "+" as usual with ggplot() objects.

nrow, ncol

Determines the layout by giving nrow and/or ncol, if missing, uses an auto layout

layout_matrix

Optionally specify a layout matrix, which is passed to marrangeGrob

byrow

If no layout_matrix is specified and there are multiple rows: How should the plots by layout? The order of the plots can be by-row (default) or by-col (set byrow=FALSE).

mapped_plot_args

Optionally, if given n objects to plot, a named list of vectors of size n. The name is an argument names passed to ggsurvplot. The elements of the vector will be mapped 1:1 to each object. This allows to perform batch plotting where only few arguments differ (e.g. titles A, B, C...) between the plots. Please note that only object that need plotting (survival_analysis results) are considered, not those that are already plotted (kaplan_meier_plot results)

paperwidth, paperheight, size_per_plot

You can specify the size per plot, or the full paper width and height. size_per_plot may be a number (width == height) or two-dimensional, width and height. The

kaplan_meier_plot 17

```
resulting paper size will be stored as a papersize attribute that is e.g. read by save_pdf
```

```
title, surv.plot.height, risk.table.height, ncensor.plot.height\\ Passed to arrange\_ggsurvplots
```

p_lessthan_cutoff

The lower limit below which p value will be displayed as "less than". If p_lessthan_cutoff == 0.001, the a p value of 0.002 will be displayed as is, while 0.0005 will become "p < 0.001".

Value

An object of class arrangelist, which can be printed or saved to pdf with ggsave().

kaplan_meier_plot

Kaplan Meier plots from survival results.

Description

Uses ggsurvplot from the survminer package to create publication-ready plots.

Usage

```
kaplan_meier_plot(..., mapped_plot_args = list(), p_lessthan_cutoff = 0.001)
```

Arguments

. . .

One or many SurvivalAnalysisResult objects as returned by analyse_survival and arguments that will be passed to ggsurvplot. Bare lists will be spliced. If using lists, the same argument may be contained in multiple lists; in this case, the last occurrence is used, i.e. you can first pass a list with default arguments, and then override some of them. If you want to combine two curves in one plot (ggsurvplot_combine), wrap them in in_one_kaplan_meier_plot when passing as argument here. (otherwise you will get a list with separate plots for each) In addition to all arguments supported by ggsurvplot, these arguments and shortcuts can be used additionally:

- break.time.by: breakByYear, breakByHalfYear, breakByQuarterYear, breakByMonth (numeric value only in ggsurvplot)
- xscale: scaleByYear, scaleByMonth (numeric value only in ggsurvplot)
- hazard.ratio (logical): display hazard ratios in addition to p value, complementing pval=T
- xlab: {.OS,.PFS,.TTF,.DFS}.{years,months,days}
- table.layout: clean, displays risk table only with color code and number, no grid, axes or labels. (do not forget risk.table=TRUE to see something)
- papersize: numeric vector of length 2, c(width, height), unit inches. kaplan_meier_plot will store a "papersize" attribute with this value which is read by save_pdf

• ggplot.add: ggplot2 object to add to the ggplot plot part of the created KM plot. One common use case is manual specification of the line type, which is currently not possible with ggsurvplot. The passed object can be result of "+" operations will be added via "+" as usual with ggplot() objects.

mapped_plot_args

Optionally, if given n objects to plot, a named list of vectors of size n. The name is an argument names passed to ggsurvplot. The elements of the vector will be mapped 1:1 to each object. This allows to perform batch plotting where only few arguments differ (e.g. titles A, B, C...) between the plots.

p_lessthan_cutoff

The lower limit below which p value will be displayed as "less than". If p_lessthan_cutoff == 0.001, the a p value of 0.002 will be displayed as is, while 0.0005 will become "p < 0.001".

Value

If given one result to plot, one ggsurvplot object; if given more than one result, a list of ggsurvplot objects.

Examples

multivariate_as_data_frame

Turns a multivariate analysis result to a data frame

Description

Extracts useful information into a data frame which is ready for printing or further analysis

Usage

```
multivariate_as_data_frame(result, factor_id_sep = ":", sort_by = NULL)
```

Arguments

result
factor_id_sep

An object of class "SurvivalAnalysisMultivariateResult" as returned by analyse_multivariate

The frame contains one column "factor.id" which is a composite of covariate name and, if categorical, the factor level (one line for each factor level except for the reference level)

sort_by

A vars() list of one or more symbolic column names. This frame contains the variables "Lower_CI", "HR", "Upper_CI", "Inv_Lower_CI", "Inv_HR", "Inv_Upper_CI", "p". You can choose to sort by any combination. Use desc() to sort a variable in descending order.

Value

A tibble.

```
pluck_multivariate_analysis
```

Access individual components of multivariate survival analysis

Description

Allows access to the analyse_multivariate result object.

Usage

```
pluck_multivariate_analysis(result, term)
```

Arguments

result

 $An object of class \ Survival Analysis Multivariate Result as \ returned \ by \ analyse _multivariate$

term The item to be retrieved:

- "coxph" containing the result of the coxph function
- "summary" containing the result of the summary of the "coxph" result
- "summary_data_frame" containing summary as a data frame (see multivariate_as_data_frame)
- "p" A vector of p values for the covariates, equivalent to the "p" column of "summary_data_frame"
- "overall" A named list with human-readable labels giving information about the overall fit, including the three flavors of p values contained in "summary"

Value

object as specified by term, or NULL if not contained in result

Examples

```
pluck_survival_analysis
```

Access individual components of univariate survival analysis

Description

Allows access to the analyse_survival result object.

Usage

```
pluck_survival_analysis(result, term)
```

Arguments

result

An object of class SurvivalAnalysisUnivariateResult as returned by analyse_survival

term

The item to be retrieved:

- "survfit" containing the result of the survfit function
- "survdiff" containing the result of the survdiff function
- "survfit_overall" containing the result of the survfit function without terms, i.e. the full group not comparing subgroups
- "coxph" containing the result of the coxph function
- "p" The log-rank p value (if by provided at least two strata)

Value

object as specified by term, or NULL if not contained in result

Examples

```
library(magrittr)
library(dplyr)
survival::aml %>%
   analyse_survival(vars(time, status), x) %>%
   pluck_survival_analysis("p") %>%
   print
```

```
\verb"print.SurvivalAnalysisMultivariateResult"
```

Print the essentials of a SurvivalAnalySurvivalAnalysisMultivariateResult

Description

Print the essentials of a SurvivalAnalySurvivalAnalysisMultivariateResult

Usage

```
## S3 method for class 'SurvivalAnalysisMultivariateResult'
print(x, ..., p_precision = 3, hr_precision = 2, p_less_than_cutoff = 0.001)
```

Arguments

Value

The formatted string, invisibly.

```
print.SurvivalAnalysisUnivariateResult
```

Print the essentials of a SurvivalAnalysisUnivariateResult

Description

Print the essentials of a SurvivalAnalysisUnivariateResult

Usage

```
## $3 method for class 'SurvivalAnalysisUnivariateResult'
print(
    X,
    ...,
    label = NULL,
    p_precision = 3,
    hr_precision = 2,
    time_precision = 1,
    include_end_separator = FALSE,
    timespan_unit = c("days", "months", "years")
)
```

Arguments

```
x The result generated by analyse_survival
... Further arguments passed from other methods.
label A label describing the result
p_precision, hr_precision, time_precision
Precision with which to print floating point values
```

22 survival_data_frames

```
include_end_separator
Append "\n—\n"? Comes handy if printing multiple results following each other timespan_unit
Unit for time spans: "days", "months" or "years".
```

Value

The formatted string, invisibly.

Description

Extract results from univariate survival analysis structured as data frames

Usage

```
survival_data_frames(
  result,
  format_numbers = TRUE,
  p_precision = 3,
  hr_precision = 2,
  p_less_than_cutoff = 0.001,
  time_precision = 1,
  timespan_unit = c("days", "months", "years")
```

Arguments

Value

A named list list of data frame objects:

- cohortMetadata: information about the full cohort
- if there are strata (analysis performed "by" a covariate):
 - strataMetadata: information about each stratum

survival_essentials 23

- hazardRatios: hazard ratios for combinations of strata
- only if there are more than two strata:
 - * pairwisePValues: Matrix of pairwise (uncorrected) p values

survival_essentials Convenience for

Convenience formatting and printing of result

Description

Takes the given result, formats and prints it

Usage

```
survival_essentials(
  result,
  label = NULL,
  p_precision = 3,
  hr_precision = 2,
  time_precision = 1,
  include_end_separator = TRUE,
  timespan_unit = "days",
  print = TRUE
)
```

Arguments

Value

The formatted string, invisibly. Ready for output with cat or saving to a file.

24 write_survival

survival_rates

Compute survival rates by KM estimate for given time points for an univariate survival analysis

Description

Compute survival rates by KM estimate for given time points for an univariate survival analysis

Usage

```
survival_rates(
  result,
  time_points,
  percentage_decimal_places = 1,
  time_precision = 0,
  timespan_unit = c("days", "months", "years")
```

Arguments

Value

A data frame with time, number at risk, number with event, survival rate with CI, and time and rate formatted for printing

write_survival

 $Print\ the\ essentials\ of\ a\ Survival Analysis\ Univariate Result.$

Description

Write complete textual information for one or multiple survival analysis results in a text file.

write_survival_rates 25

Usage

```
write_survival(
    ...,
    file,
    label = NULL,
    p_precision = 3,
    hr_precision = 2,
    time_precision = 1,
    include_end_separator = FALSE,
    timespan_unit = c("days", "months", "years")
)
```

Arguments

Details

As write_survival takes potentially multiple objects, it cannot return its input in a cleanly defined way. You can still elegantly combine write_survival in a pipe followed by kaplan_meier_plot or kaplan_meier_grid for a single input object if you apply the tee pipe operator %T>% in front of write_survival.

Value

None (invisible NULL).

write_survival_rates Write survival rates for one or multiple survival analysis results in a CSV file.

Description

As write_survival takes potentially multiple objects, it cannot return its input in a cleanly defined way. You can still elegantly combine write_survival in a pipe followed by kaplan_meier_plot or kaplan_meier_grid for a single input object if you apply the tee pipe operator %T>% in front of write_survival.

26 write_survival_rates

Usage

```
write_survival_rates(
    ...,
    file,
    time_points,
    label = NULL,
    writer = write.csv,
    writer_args = list(),
    percentage_decimal_places = 1,
    time_precision = 0,
    timespan_unit = c("days", "months", "years")
)
```

Arguments

... Results generated by analyse_survival, or lists of such objects

file A connection, or a character string naming the file to print to. (see cat)

label A label describing the result, or a vector of the same size as results in ... (will

then be mapped 1:1). Recommended to distinguish result lines from multiple

results in ...

writer A writer function such as write.csv

writer_args Parameters to pass to the writer function

 $\verb"percentage_decimal_places", \verb"time_precision"$

Precision with which to print floating point values in their label form

timespan_unit Unit for time spans: "days", "months" or "years"

Value

None (invisible NULL).
