

Package ‘svars’

July 23, 2025

Type Package

Title Data-Driven Identification of SVAR Models

Version 1.3.11

Date 2023-01-29

Author Alexander Lange [aut, cre],
Bernhard Dalheimer [aut],
Helmut Herwartz [aut],
Simone Maxand [aut],
Hannes Riebl [ctb]

Maintainer Alexander Lange <alexander.lange@uni-goettingen.de>

Description Implements data-driven identification methods for structural vector autoregressive (SVAR) models as described in Lange et al. (2021) <doi:10.18637/jss.v097.i05>. Based on an existing VAR model object (provided by e.g. VAR() from the 'vars' package), the structural impact matrix is obtained via data-driven identification techniques (i.e. changes in volatility (Rigobon, R. (2003) <doi:10.1162/003465303772815727>), patterns of GARCH (Normadin, M., Phaneuf, L. (2004) <doi:10.1016/j.jmoneco.2003.11.002>), independent component analysis (Matte-son, D. S., Tsay, R. S., (2013) <doi:10.1080/01621459.2016.1150851>), least dependent innovations (Herwartz, H., Ploedt, M., (2016) <doi:10.1016/j.jimonfin.2015.11.001>), smooth transition in variances (Luetkepohl, H., Netsuna-jev, A. (2017) <doi:10.1016/j.jedc.2017.09.001>) or non-Gaussian maximum likelihood (Lanne, M., Meitz, M., Saikkonen, P. (2017) <doi:10.1016/j.jeconom.2016.06.002>)).

Depends R (>= 2.10), vars (>= 1.5.3)

ba.boot	<i>Bootstrap after Bootstrap</i>
---------	----------------------------------

Description

Bootstrap intervals based on bias-adjusted estimators

Usage

ba.boot(x, nc = 1)

Arguments

x	SVAR object of class "sboot"
nc	Integer. Number of processor cores

Value

A list of class "sboot" with elements

true	Point estimate of impulse response functions
bootstrap	List of length "nboot" holding bootstrap impulse response functions
SE	Bootstrapped standard errors of estimated covariance decomposition (only if "x" has method "Cramer von-Mises", or "Distance covariances")
nboot	Number of bootstrap iterations
b_length	Length of each block
point_estimate	Point estimate of covariance decomposition
boot_mean	Mean of bootstrapped covariance decompositions
signrest	Evaluated sign pattern
sign_complete	Frequency of appearance of the complete sign pattern in all bootstrapped covariance decompositions
sign_part	Frequency of bootstrapped covariance decompositions which conform the complete predetermined sign pattern. If signrest=NULL, the frequency of bootstrapped covariance decompositions that hold the same sign pattern as the point estimate is provided.
sign_part	Frequency of single shocks in all bootstrapped covariance decompositions which accord to a specific predetermined sign pattern
cov_bs	Covariance matrix of bootstrapped parameter in impact relations matrix
method	Used bootstrap method
VAR	Estimated input VAR object

```

```
summary(bb)
plot(bb, lowerq = 0.16, upperq = 0.84)

# Bias-adjusted bootstrap
bb2 <- ba.boot(bb, nc = 1)
plot(bb2, lowerq = 0.16, upperq = 0.84)
```

cf

Counterfactuals for SVAR Models

Description

Calculation of Counterfactuals for an identified SVAR object 'svars' derived by function `id.st()`, `id.cvm()`, `id.cv()`, `id.dc()` or `id.ngml()`.

Usage

```
cf(x, series = 1, transition = 0)
```

Arguments

x	SVAR object of class "svars"
series	Integer. indicating the series for which the counterfactuals should be calculated.
transition	Numeric. Value from [0, 1] indicating how many initial values should be discarded, i.e., 0.1 means that the first 10 per cent observations of the sample are considered as transient.

Value

A list with class attribute "hd" holding the Counterfactuals as data frame.

x1 <- id.dc(v1)
x2 <- cf(x1, series = 2)
plot(x2)
```

chow.test

*Chow Test for Structural Break***Description**

The Chow test for structural change is implemented as sample-split and break-point test (see Luetkepohl and Kraetzig, 2004, p. 135). An estimated VAR model and the presupposed structural break need to be provided.

Usage

```
chow.test(
  x,
  SB,
  nboot = 500,
  start = NULL,
  end = NULL,
  frequency = NULL,
  format = NULL,
  dateVector = NULL
)
```

Arguments

x	An object of class 'vars', 'vec2var', 'nlVar'. Estimated VAR object. Or an object of class 'chowpretest' from stability()
SB	Integer, vector or date character. The structural break is specified either by an integer (number of observations in the pre-break period), a vector of ts() frequencies if a ts object is used in the VAR or a date character. If a date character is provided, either a date vector containing the whole time line in the corresponding format or common time parameters need to be provided
nboot	Integer. Number of bootstrap iterations to calculate quantiles and p-values
start	Character. Start of the time series (only if dateVector is empty)
end	Character. End of the time series (only if dateVector is empty)
frequency	Character. Frequency of the time series (only if dateVector is empty)
format	Character. Date format (only if dateVector is empty)
dateVector	Vector. Vector of time periods containing SB in corresponding format

Value

A list of class "chow" with elements

lambda_bp	Test statistic of the Chow test with break point
testcrit_bp	Critical value of the test statistic lambda_bp
p.value_bp	p-value of the test statistic lambda_bp

lambda_sp	Test statistic of the Chow test with sample split
testcrit_sp	Critical value of the test statistic lambda_sp
p.value_sp	p-value of the test statistic lambda_sp
SB	Structural break tested
SBcharacter	Structural break tested as character
p	Number of lags used

fevd

*Forecast error variance decomposition for SVAR Models***Description**

Calculation of forecast error variance decomposition for an identified SVAR object 'svars' derived by function `id.st()`, `id.cvm()`, `id.cv()`, `id.dc()` or `id.ngml()`.

Usage

```
## S3 method for class 'svars'
fevd(x, n.ahead = 10, ...)
```

Arguments

<code>x</code>	SVAR object of class "svars".
<code>n.ahead</code>	Integer specifying the steps.
<code>...</code>	Currently not used.

Value

A list with class attribute "svarfevd" holding the forecast error variance decompositions as data frames.

```

hd

*Historical decomposition for SVAR Models***Description**

Calculation of historical decomposition for an identified SVAR object 'svars' derived by function `id.st()`, `id.cvm()`, `id.cv()`, `id.dc()` or `id.ngml()`.

Usage

```
hd(x, series = 1, transition = 0)
```

Arguments

<code>x</code>	SVAR object of class "svars"
<code>series</code>	Integer. indicating the series that should be decomposed.
<code>transition</code>	Numeric. Value from [0, 1] indicating how many initial values should be discarded, i.e., 0.1 means that the first 10 per cent observations of the sample are considered as transient.

Value

A list with class attribute "hd" holding the historical decomposition as data frame.

id.chol

*Recursive identification of SVAR models via Cholesky decomposition***Description**

Given an estimated VAR model, this function uses the Cholesky decomposition to identify the structural impact matrix B of the corresponding SVAR model

$$y_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + u_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + B \epsilon_t.$$

Matrix B corresponds to the decomposition of the least squares covariance matrix $\Sigma_u = B \Lambda_t B'$.

Usage

```
id.chol(x, order_k = NULL)
```

Arguments

x An object of class 'vars', 'vec2var', 'nlVar'. Estimated VAR object

order_k Vector. Vector of characters or integers specifying the assumed structure of the recursive causality. Change the causal ordering in the instantaneous effects without permuting variables and re-estimating the VAR model.

Value

A list of class "svars" with elements

B	Estimated structural impact matrix B, i.e. unique decomposition of the covariance matrix of reduced form residuals
n	Number of observations
method	Method applied for identification
order_k	Ordering of the variables as assumed for recursive causality
A_hat	Estimated VAR parameter
type	Type of the VAR model, e.g. 'const'
y	Data matrix
p	Number of lags
K	Dimension of the VAR
VAR	Estimated input VAR object

References

Luetkepohl, H., 2005. New introduction to multiple time series analysis, Springer-Verlag, Berlin.

See Also

For alternative identification approaches see [id.st](#), [id.cvm](#), [id.cv](#), [id.dc](#) or [id.ngml](#)

Examples

```
# data contains quarterly observations from 1965Q1 to 2008Q3
# x = output gap
# pi = inflation
# i = interest rates
set.seed(23211)
v1 <- vars::VAR(USA, lag.max = 10, ic = "AIC" )
x1 <- id.chol(v1)
x2 <- id.chol(v1, order_k = c("pi", "x", "i")) ## order_k = c(2,1,3)
summary(x1)

# impulse response analysis
i1 <- irf(x1, n.ahead = 30)
i2 <- irf(x2, n.ahead = 30)
plot(i1, scales = 'free_y')
plot(i2, scales = 'free_y')
```

id.cv

Identification of SVAR models based on Changes in volatility (CV)

Description

Given an estimated VAR model, this function applies changes in volatility to identify the structural impact matrix B of the corresponding SVAR model

$$y_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + u_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + B \epsilon_t.$$

Matrix B corresponds to the decomposition of the pre-break covariance matrix $\Sigma_1 = BB'$. The post-break covariance corresponds to $\Sigma_2 = B\Lambda B'$ where Λ is the estimated unconditional heteroskedasticity matrix.

Usage

```
id.cv(
  x,
  SB,
  SB2 = NULL,
  start = NULL,
  end = NULL,
  frequency = NULL,
  format = NULL,
  dateVector = NULL,
  max.iter = 50,
```

```

    crit = 0.001,
    restriction_matrix = NULL
  )

```

Arguments

x	An object of class 'vars', 'vec2var', 'nlVar'. Estimated VAR object
SB	Integer, vector or date character. The structural break is specified either by an integer (number of observations in the pre-break period), a vector of ts() frequencies if a ts object is used in the VAR or a date character. If a date character is provided, either a date vector containing the whole time line in the corresponding format (see examples) or common time parameters need to be provided
SB2	Integer, vector or date character. Optional if the model should be estimated with two volatility regimes. The structural break is specified either by an integer (number of observations in the pre-break period), a vector of ts() frequencies if a ts object is used in the VAR or a date character. If a date character is provided, either a date vector containing the whole time line in the corresponding format (see examples) or common time parameters need to be provided
start	Character. Start of the time series (only if dateVector is empty)
end	Character. End of the time series (only if dateVector is empty)
frequency	Character. Frequency of the time series (only if dateVector is empty)
format	Character. Date format (only if dateVector is empty)
dateVector	Vector. Vector of time periods containing SB in corresponding format
max.iter	Integer. Number of maximum GLS iterations
crit	Numeric. Critical value for the precision of the GLS estimation
restriction_matrix	Matrix. A matrix containing presupposed entries for matrix B, NA if no restriction is imposed (entries to be estimated). Alternatively, a $K^2 \times K^2$ matrix can be passed, where ones on the diagonal designate unrestricted and zeros restricted coefficients. (as suggested in Luetkepohl, 2017, section 5.2.1).

Value

A list of class "svars" with elements

Lambda	Estimated unconditional heteroscedasticity matrix Λ
Lambda_SE	Matrix of standard errors of Lambda
B	Estimated structural impact matrix B, i.e. unique decomposition of the covariance matrix of reduced form residuals
B_SE	Standard errors of matrix B
n	Number of observations
Fish	Observed Fisher information matrix
Lik	Function value of likelihood

wald_statistic	Results of sequential Wald-type identification test on equal eigenvalues as described in Luetkepohl et. al. (2021). In case of more than two regimes, pairwise Wald-type tests of equal diagonal elements in the Lambda matrices are performed.
iteration	Number of GLS estimations
method	Method applied for identification
SB	Structural break (number of observations)
A_hat	Estimated VAR parameter via GLS
type	Type of the VAR model, e.g. 'const'
SBcharacter	Structural break (date; if provided in function arguments)
restrictions	Number of specified restrictions
restriction_matrix	Specified restriction matrix
y	Data matrix
p	Number of lags
K	Dimension of the VAR
VAR	Estimated input VAR object

id.cvm

Independence-based identification of SVAR models via Cramer-von Mises (CVM) distance

Description

Given an estimated VAR model, this function applies independence-based identification for the structural impact matrix B of the corresponding SVAR model

$$y_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + u_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + B \epsilon_t.$$

Matrix B corresponds to the unique decomposition of the least squares covariance matrix $\Sigma_u = BB'$ if the vector of structural shocks ϵ_t contains at most one Gaussian shock (Comon, 1994). A nonparametric dependence measure, the Cramer-von Mises distance (Genest and Remillard, 2004), determines least dependent structural shocks. The minimum is obtained by a two step optimization algorithm similar to the technique described in Herwartz and Ploedt (2016).

Usage

```
id.cvm(x, dd = NULL, itermax = 500, steptol = 100, iter2 = 75)
```

Arguments

<code>x</code>	An object of class 'vars', 'vec2var', 'nlVar'. Estimated VAR object
<code>dd</code>	Object of class 'indepTestDist' (generated by 'indepTest' from package 'copula'). A simulated independent sample of the same size as the data. If not supplied, it will be calculated by the function
<code>itermax</code>	Integer. IMaximum number of iterations for DEoptim
<code>steptol</code>	Numeric. Tolerance for steps without improvement for DEoptim
<code>iter2</code>	Integer. Number of iterations for the second optimization

Value

A list of class "svars" with elements

<code>B</code>	Estimated structural impact matrix B , i.e. unique decomposition of the covariance matrix of reduced form errors
<code>A_hat</code>	Estimated VAR parameter
<code>method</code>	Method applied for identification
<code>n</code>	Number of observations
<code>type</code>	Type of the VAR model, e.g. 'const'
<code>y</code>	Data matrix
<code>p</code>	Number of lags
<code>K</code>	Dimension of the VAR
<code>rotation_angles</code>	Rotation angles, which lead to maximum independence
<code>inc</code>	Indicator. 1 = second optimization increased the estimation precision. 0 = second optimization did not increase the estimation precision
<code>test.stats</code>	Computed test statistics of independence test
<code>iter1</code>	Number of iterations of first optimization
<code>test1</code>	Minimum test statistic from first optimization
<code>test2</code>	Minimum test statistic from second optimization
<code>VAR</code>	Estimated input VAR object

id.dc

Independence-based identification of SVAR models build on distance covariances (DC) statistic

Description

Given an estimated VAR model, this function applies independence-based identification for the structural impact matrix B of the corresponding SVAR model

$$y_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + u_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + B \epsilon_t.$$

Matrix B corresponds to the unique decomposition of the least squares covariance matrix $\Sigma_u = BB'$ if the vector of structural shocks ϵ_t contains at most one Gaussian shock (Comon, 1994). A nonparametric dependence measure, the distance covariance (Szekely et al, 2007), determines least dependent structural shocks. The algorithm described in Matteson and Tsay (2013) is applied to calculate the matrix B .

Usage

```
id.dc(x, PIT = FALSE)
```

Arguments

<code>x</code>	An object of class 'vars', 'vec2var', 'nlVar'. Estimated VAR object
<code>PIT</code>	Logical. If PIT='TRUE', the distribution and density of the independent components are estimated using gaussian kernel density estimates

Value

A list of class "svars" with elements

<code>B</code>	Estimated structural impact matrix B , i.e. unique decomposition of the covariance matrix of reduced form errors
<code>A_hat</code>	Estimated VAR parameter
<code>method</code>	Method applied for identification
<code>n</code>	Number of observations
<code>type</code>	Type of the VAR model, e.g. 'const'
<code>y</code>	Data matrix
<code>p</code>	Number of lags
<code>K</code>	Dimension of the VAR
<code>PIT</code>	Logical, if PIT is used
<code>VAR</code>	Estimated input VAR object

id.garch

*Identification of SVAR models through patterns of GARCH***Description**

Given an estimated VAR model, this function uses GARCH-type variances to identify the structural impact matrix B of the corresponding SVAR model

$$y_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + u_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + B \epsilon_t.$$

Matrix B corresponds to the decomposition of the least squares covariance matrix $\Sigma_u = B \Lambda_t B'$, where Λ_t is the estimated conditional heteroskedasticity matrix.

Usage

```
id.garch(
  x,
  max.iter = 5,
  crit = 0.001,
  restriction_matrix = NULL,
  start_iter = 50
)
```

Arguments

x	An object of class 'vars', 'vec2var', 'nlVar'. Estimated VAR object
max.iter	Integer. Number of maximum likelihood optimizations
crit	Numeric. Critical value for the precision of the iterative procedure

restriction_matrix	Matrix. A matrix containing presupposed entries for matrix B, NA if no restriction is imposed (entries to be estimated). Alternatively, a $K^2 \times K^2$ matrix can be passed, where ones on the diagonal designate unrestricted and zeros restricted coefficients. (as suggested in Luetkepohl, 2017, section 5.2.1).
start_iter	Numeric. Number of random candidate initial values for univariate GRACH(1,1) optimization.

Value

A list of class "svars" with elements

B	Estimated structural impact matrix B, i.e. unique decomposition of the covariance matrix of reduced form residuals
B_SE	Standard errors of matrix B
GARCH_parameter	Estimated GARCH parameters of univariate GARCH models
GARCH_SE	Standard errors of GARCH parameters
n	Number of observations
Fish	Observed Fisher information matrix
Lik	Function value of likelihood
iteration	Number of likelihood optimizations
method	Method applied for identification
A_hat	Estimated VAR parameter via GLS
type	Type of the VAR model, e.g. 'const'
restrictions	Number of specified restrictions
restriction_matrix	Specified restriction matrix
y	Data matrix
p	Number of lags
K	Dimension of the VAR
VAR	Estimated input VAR object
I_test	Results of a series of sequential tests on the number of heteroskedastic shocks present in the system as described in Luetkepohl and Milunovich (2016).

id.ngml

Non-Gaussian maximum likelihood (NGML) identification of SVAR models

Description

Given an estimated VAR model, this function applies identification by means of a non-Gaussian likelihood for the structural impact matrix B of the corresponding SVAR model

$$y_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + u_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + B \epsilon_t.$$

Matrix B corresponds to the unique decomposition of the least squares covariance matrix $\Sigma_u = BB'$ if the vector of structural shocks ϵ_t contains at most one Gaussian shock (Comon, 94). A likelihood function of independent t-distributed structural shocks $\epsilon_t = B^{-1}u_t$ is maximized with respect to the entries of B and the degrees of freedom of the t-distribution (Lanne et al., 2017).

Usage

```
id.ngml(x, stage3 = FALSE, restriction_matrix = NULL)
```

Arguments

<code>x</code>	An object of class 'vars', 'vec2var', 'nlVar'. Estimated VAR object
<code>stage3</code>	Logical. If stage3="TRUE", the VAR parameters are estimated via non-gaussian maximum likelihood (computationally demanding)
<code>restriction_matrix</code>	Matrix. A matrix containing presupposed entries for matrix B, NA if no restriction is imposed (entries to be estimated). Alternatively, a $K^2 \times K^2$ matrix can be passed, where ones on the diagonal designate unrestricted and zeros restricted coefficients. (as suggested in Luetkepohl, 2017, section 5.2.1).

Value

A list of class "svars" with elements

<code>B</code>	Estimated structural impact matrix B, i.e. unique decomposition of the covariance matrix of reduced form errors
<code>sigma</code>	Estimated scale of the standardized matrix B_stand, i.e. $B = B_{stand} * diag(\sigma_1, \dots, \sigma_K)$
<code>sigma_SE</code>	Standard errors of the scale
<code>df</code>	Estimated degrees of freedom
<code>df_SE</code>	Standard errors of the degrees of freedom
<code>Fish</code>	Observed Fisher information matrix
<code>A_hat</code>	Estimated VAR parameter via ML
<code>B_stand</code>	Estimated standardized structural impact matrix
<code>B_stand_SE</code>	Standard errors of standardized matrix B_stand
<code>Lik</code>	Function value of likelihood
<code>method</code>	Method applied for identification
<code>n</code>	Number of observations
<code>type</code>	Type of the VAR model, e.g. 'const'
<code>y</code>	Data matrix
<code>p</code>	Number of lags
<code>K</code>	Dimension of the VAR
<code>restrictions</code>	Number of specified restrictions
<code>restriction_matrix</code>	Specified restriction matrix
<code>stage3</code>	Logical, whether Stage 3 is performed
<code>VAR</code>	Estimated input VAR object

id.st

Identification of SVAR models by means of a smooth transition (ST) in covariance

Description

Given an estimated VAR model, this function uses a smooth transition in the covariance to identify the structural impact matrix B of the corresponding SVAR model

$$y_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + u_t = c_t + A_1 y_{t-1} + \dots + A_p y_{t-p} + B \epsilon_t.$$

Matrix B corresponds to the decomposition of the pre-break covariance matrix $\Sigma_1 = BB'$. The post-break covariance corresponds to $\Sigma_2 = B\Lambda B'$ where Λ is the estimated heteroskedasticity matrix.

Usage

```
id.st(
  x,
  c_lower = 0.3,
  c_upper = 0.7,
  c_step = 5,
  c_fix = NULL,
  transition_variable = NULL,
  gamma_lower = -3,
  gamma_upper = 2,
```

```

gamma_step = 0.5,
gamma_fix = NULL,
nc = 1,
max.iter = 5,
crit = 0.001,
restriction_matrix = NULL,
lr_test = FALSE
)

```

Arguments

<code>x</code>	An object of class 'vars', 'vec2var', 'nlVar'. Estimated VAR object
<code>c_lower</code>	Numeric. Starting point for the algorithm to start searching for the volatility shift. Default is $0.3 \times (\text{Total number of observations})$
<code>c_upper</code>	Numeric. Ending point for the algorithm to stop searching for the volatility shift. Default is $0.7 \times (\text{Total number of observations})$. Note that in case of a stochastic transition variable, the input requires an absolute value
<code>c_step</code>	Integer. Step width of c. Default is 5. Note that in case of a stochastic transition variable, the input requires an absolute value
<code>c_fix</code>	Numeric. If the transition point is known, it can be passed as an argument where transition point = Number of observations - c_fix
<code>transition_variable</code>	A numeric vector that represents the transition variable. By default (NULL), the time is used as transition variable. Note that c_lower, c_upper, c_step and/or c_fix have to be adjusted to the specified transition variable
<code>gamma_lower</code>	Numeric. Lower bound for gamma. Small values indicate a flat transition function. Default is -3
<code>gamma_upper</code>	Numeric. Upper bound for gamma. Large values indicate a steep transition function. Default is 2
<code>gamma_step</code>	Numeric. Step width of gamma. Default is 0.5
<code>gamma_fix</code>	Numeric. A fixed value for gamma, alternative to gamma found by the function
<code>nc</code>	Integer. Number of processor cores Note that the smooth transition model is computationally extremely demanding.
<code>max.iter</code>	Integer. Number of maximum GLS iterations
<code>crit</code>	Numeric. Critical value for the precision of the GLS estimation
<code>restriction_matrix</code>	Matrix. A matrix containing presupposed entries for matrix B, NA if no restriction is imposed (entries to be estimated). Alternatively, a $K^2 \times K^2$ matrix can be passed, where ones on the diagonal designate unrestricted and zeros restricted coefficients. (as suggested in Luetkepohl, 2017, section 5.2.1).
<code>lr_test</code>	Logical. Indicates whether the restricted model should be tested against the unrestricted model via a likelihood ratio test

Value

A list of class "svars" with elements

Lambda	Estimated heteroscedasticity matrix Λ
Lambda_SE	Matrix of standard errors of Lambda
B	Estimated structural impact matrix B, i.e. unique decomposition of the covariance matrix of reduced form residuals
B_SE	Standard errors of matrix B
n	Number of observations
Fish	Observed Fisher information matrix
Lik	Function value of likelihood
wald_statistic	Results of pairwise Wald tests
iteration	Number of GLS estimations
method	Method applied for identification
est_c	Structural break (number of observations)
est_g	Transition coefficient
transition_variable	Vector of transition variable
comb	Number of all grid combinations of gamma and c
transition_function	Vector of transition function
A_hat	Estimated VAR parameter via GLS
type	Type of the VAR model e.g., 'const'
y	Data matrix
p	Number of lags
K	Dimension of the VAR
restrictions	Number of specified restrictions
restriction_matrix	Specified restriction matrix
lr_test	Logical, whether a likelihood ratio test is performed
lRatioTest	Results of likelihood ratio test
VAR	Estimated input VAR object

irf

Impulse Response Functions for SVAR Models

Description

Calculation of impulse response functions for an identified SVAR object 'svars' derived by function `id.cvm()`, `id.cv()`, `id.dc()`, `id.ngml()` or `id.st()`.

Usage

```
## S3 method for class 'svars'
irf(x, ..., n.ahead = 20)
```

Arguments

x	SVAR object of class "svars".
...	Currently not used.
n.ahead	Integer specifying the steps.

Value

A list with class attribute "svarirf" holding the impulse response functions as data frame.

References

Luetkepohl, H., 2005. New introduction to multiple time series analysis, Springer-Verlag, Berlin.

x2 <- irf(x1, n.ahead = 20)
plot(x2)
```

js.test

Chi-square test for joint hypotheses

Description

Based on an existing bootstrap object, the test statistic allows to test joint hypotheses for selected entries of the structural matrix B. The test statistic reads as

$$(Rvec(\hat{B}) - r)' R(\widehat{Cov}[vec(B^*)])^{-1} R' (Rvec(\hat{b} - r)) \sim \chi_J^2,$$

where $\widehat{Cov}[vec(B^*)]$ is the estimated covariance of vectorized bootstrap estimates of structural parameters. The composite null hypothesis is $H_0 : Rvec(B) = r$.

Usage

```
js.test(x, R, r = NULL)
```

Arguments

x	Object of class 'sboot'
R	A J*K^2 selection matrix, where J is the number of hypotheses and K the number of time series.
r	A J*1 vector of restrictions

Value

A list of class "jstest" with elements

test_statistic	Test statistic
p_value	P-value
R	Selection matrix
r	Vector of restrictions

c.test <- js.test(bb, R)
summary(c.test)
```

Description

A five dimensional time series model which is commonly used to analyze the interaction between monetary policy and the stock market.
Monthly observations from 1970M1 to 2007M6:

- q Linearly detrended log of an industrial production index
- pi Annual change in the log of consumer prices (CPI index) (x100)
- c annual change in the log of the World Bank (non energy) commodity price index (x100)
- s Log of the real S&P500 stock price index deflated by the consumer price index to measure the real stock prices; the series
- r Interest rate on Federal funds

All series, with exception of the commodity price index (c), are taken from the FRED database and transformed as in Luetkepohl & Netsunajev (2017). The commodity price index comes from the World Bank. A more detailed description of the data and a corresponding VAR model implementation can be found in Luetkepohl & Netsunajev (2017).

Usage

LN

Format

A data.frame containing 450 observations on 5 variables.

Source

Luetkepohl H., Netsunajev A., 2017. "Structural vector autoregressions with smooth transition in variances."
Journal of Economic Dynamics and Control, 84, 43 - 57. ISSN 0165-1889.

mb.boot

Moving block bootstrap for IRFs of identified SVARs

Description

Calculating confidence bands for impulse response via moving block bootstrap

Usage

```
mb.boot(
  x,
  design = "recursive",
  b.length = 15,
  n.ahead = 20,
  nboot = 500,
  nc = 1,
  dd = NULL,
  signrest = NULL,
  signcheck = TRUE,
  itermax = 300,
  steptol = 200,
  iter2 = 50
)
```

Arguments

x	SVAR object of class "svars"
design	character. If design="fixed", a fixed design bootstrap is performed. If design="recursive", a recursive design bootstrap is performed.
b.length	Integer. Length of each block
n.ahead	Integer specifying the steps
nboot	Integer. Number of bootstrap iterations
nc	Integer. Number of processor cores
dd	Object of class 'indepTestDist'. A simulated independent sample of the same size as the data. If not supplied, it will be calculated by the function
signrest	A list with vectors containing 1 and -1, e.g. c(1,-1,1), indicating a sign pattern of specific shocks to be tested with the help of the bootstrap samples.
signcheck	Boolean. Whether the sign pattern should be checked for each bootstrap iteration. Note that this procedure is computationally extremely demanding for high dimensional VARs, since the number of possible permutations of B is $K!$, where K is the number of variables in the VAR.
itermax	Integer. Maximum number of iterations for DEoptim
steptol	Numeric. Tolerance for steps without improvement for DEoptim
iter2	Integer. Number of iterations for the second optimization

Value

A list of class "sboot" with elements

true	Point estimate of impulse response functions
bootstrap	List of length "nboot" holding bootstrap impulse response functions
SE	Bootstrapped standard errors of estimated covariance decomposition (only if "x" has method "Cramer von-Mises", or "Distance covariances")
nboot	Number of bootstrap iterations
design	character. Whether a fixed design or recursive design bootstrap is performed
b_length	Length of each block
point_estimate	Point estimate of covariance decomposition
boot_mean	Mean of bootstrapped covariance decompositions
signrest	Evaluated sign pattern
sign_complete	Frequency of appearance of the complete sign pattern in all bootstrapped covariance decompositions
sign_part	Frequency of bootstrapped covariance decompositions which conform the complete predetermined sign pattern. If signrest=NULL, the frequency of bootstrapped covariance decompositions that hold the same sign pattern as the point estimate is provided.
sign_part	Frequency of single shocks in all bootstrapped covariance decompositions which accord to a specific predetermined sign pattern

cov_bs	Covariance matrix of bootstrapped parameter in impact relations matrix
method	Used bootstrap method
VAR	Estimated input VAR object

stability

*Structural stability of a VAR(p)***Description**

Computes an empirical fluctuation process according to a specified method from the generalized fluctuation test framework. The test utilises the function `efp()` and its methods from package ‘`strucchange`’. Additionally, the function provides the option to compute a multivariate chow test.

Usage

```
## S3 method for class 'varest'
stability(
  x,
  type = c("OLS-CUSUM", "Rec-CUSUM", "Rec-MOSUM", "OLS-MOSUM", "RE", "ME", "Score-CUSUM",
           "Score-MOSUM", "fluctuation", "mv-chow-test"),
  h = 0.15,
  dynamic = FALSE,
  rescale = TRUE,
  ...
)
```

Arguments

<code>x</code>	Object of class ‘ <code>varest</code> ’; generated by <code>VAR()</code> .
<code>type</code>	Specifies which type of fluctuation process will be computed, the default is ‘ <code>OLS-CUSUM</code> ’. For details see: efp and chow.test .
<code>h</code>	A numeric from interval (0,1) specifying the bandwidth. Determines the size of the data window relative to sample size (for ‘ <code>MOSUM</code> ’, ‘ <code>ME</code> ’ and ‘ <code>mv-chow-test</code> ’ only).
<code>dynamic</code>	Logical. If ‘ <code>TRUE</code> ’ the lagged observations are included as a regressor (not if ‘ <code>type</code> ’ is ‘ <code>mv-chow-test</code> ’).
<code>rescale</code>	Logical. If ‘ <code>TRUE</code> ’ the estimates will be standardized by the regressor matrix of the corresponding subsample; if ‘ <code>FALSE</code> ’ the whole regressor matrix will be used. (only if ‘ <code>type</code> ’ is either ‘ <code>RE</code> ’ or ‘ <code>E</code> ’).
<code>...</code>	Ellipsis, is passed to <code>strucchange::sctest()</code> , as default.

Details

For details, please refer to documentation [efp](#) and [chow.test](#).

Value

A list with either class attribute ‘`varstabil`’ or ‘`chowpretest`’ holding the following elements in case of class ‘`varstabil`’:

stability	A list with objects of class 'efp'; length is equal to the dimension of the VAR.
names	Character vector containing the names of the endogenous variables.
K	An integer of the VAR dimension.

In case of class 'chowpretest' the list consists of the following elements:

teststat_bp	A vector containing the calculated break point test statistics for all considered break points.
teststat_sp	A vector containing the calculated sample split test statistics for all considered sample splits.
from	An integer specifying the first observation as possible break date.
to	An integer specifying the last observation as possible break date.
var	A list with objects of class 'varest'
break_point	Logical, if the break point test should be the benchmark for later analysis.

svars

*svars: Data-driven identification of structural VAR models***Description**

This package implements data-driven identification methods for structural vector autoregressive (SVAR) models as described in Lange et al. (2021) [doi:10.18637/jss.v097.i05](https://doi.org/10.18637/jss.v097.i05). Based on an existing VAR model object, the structural impact matrix B may be obtained via different forms of heteroskedasticity or independent components.

Details

The main functions to retrieve structural impact matrices are:

`id.cv` Identification via changes in volatility,

-

`id.cvm` Independence-based identification of SVAR models based on Cramer-von Mises distance,

-

`id.dc` Independence-based identification of SVAR models based on distance covariances,

-

`id.garch` Identification through patterns of conditional heteroskedasticity,

-

`id.ngml` Identification via Non-Gaussian maximum likelihood,

-

`id.st` Identification by means of smooth transition in covariance.

-

All of these functions require an estimated var object. Currently the classes 'vars' and 'vec2var' from the vars package, 'nlVar', which includes both VAR and VECM, from the tsDyn package as well as the list from MTS package are supported. Besides these core functions, additional tools to calculate confidence bands for impulse response functions using bootstrap techniques as well as the Chow-Test for structural changes are implemented. The USA dataset is used to showcase the functionalities in examples throughout the package.

USA

*US macroeconomic time series***Description**

The time series of output gap (x), inflation (pi) and interest rate (r) are taken from the FRED database and transformed as in Herwartz & Ploedt (2016). The trivariate time series model is commonly used to analyze monetary policy shocks.

Quarterly observations from 1965Q1 to 2008Q3:

- x Percentage log-deviation of real GDP wrt the estimate of potential output by the Congressional Budget Office
- pi Annualized quarter-on-quarter growth of the GDP deflator
- i Interest rate on Federal funds

A more detailed description of the data and a corresponding VAR model implementation can be found in Herwartz & Ploedt (2016).

Usage

USA

Format

A data.frame containing 174 observations on 3 variables.

Source

Herwartz, H. & Ploedt, M., 2016. Simulation Evidence on Theory-based and Statistical Identification under Volatility Breaks, *Oxford Bulletin of Economics and Statistics*, 78, 94-112.
Data originally from FRED database of the Federal Reserve Bank of St. Louis.

wild.boot

*Wild bootstrap for IRFs of identified SVARs***Description**

Calculating confidence bands for impulse response functions via wild bootstrap techniques (Goncalves and Kilian, 2004).

Usage

```
wild.boot(
  x,
  design = "fixed",
  distr = "rademacher",
  n.ahead = 20,
  nboot = 500,
  nc = 1,
  dd = NULL,
  signrest = NULL,
  signcheck = TRUE,
  itermax = 300,
  steptol = 200,
  iter2 = 50,
  rademacher = "deprecated"
)
```

Arguments

x	SVAR object of class "svars"
design	character. If design="fixed", a fixed design bootstrap is performed. If design="recursive", a recursive design bootstrap is performed.
distr	character. If distr="rademacher", the Rademacher distribution is used to generate the bootstrap samples. If distr="mammen", the Mammen distribution is used. If distr = "gaussian", the gaussian distribution is used.
n.ahead	Integer specifying the steps
nboot	Integer. Number of bootstrap iterations
nc	Integer. Number of processor cores
dd	Object of class 'indepTestDist'. A simulated independent sample of the same size as the data. roxIf not supplied, it will be calculated by the function
signrest	A list with vectors containing 1 and -1, e.g. c(1,-1,1), indicating a sign pattern of specific shocks to be tested with the help of the bootstrap samples.
signcheck	Boolean. Whether the sign pattern should be checked for each bootstrap iteration. Note that this procedure is computationally extremely demanding for high dimensional VARs, since the number of possible permutations of B is $K!$, where K is the number of variables in the VAR.

itermax	Integer. Maximum number of iterations for DEoptim
steptol	Integer. Tolerance for steps without improvement for DEoptim
iter2	Integer. Number of iterations for the second optimization
rademacher	deprecated, use "design" instead.

Value

A list of class "sboot" with elements

true	Point estimate of impulse response functions
bootstrap	List of length "nboot" holding bootstrap impulse response functions
SE	Bootstrapped standard errors of estimated covariance decomposition (only if "x" has method "Cramer von-Mises", or "Distance covariances")
nboot	Number of bootstrap iterations
distr	Character, whether the Gaussian, Rademacher or Mammen distribution is used in the bootstrap
design	character. Whether a fixed design or recursive design bootstrap is performed
point_estimate	Point estimate of covariance decomposition
boot_mean	Mean of bootstrapped covariance decompositions
signrest	Evaluated sign pattern
sign_complete	Frequency of appearance of the complete sign pattern in all bootstrapped covariance decompositions
sign_part	Frequency of bootstrapped covariance decompositions which conform the complete predetermined sign pattern. If signrest=NULL, the frequency of bootstrapped covariance decompositions that hold the same sign pattern as the point estimate is provided.
sign_part	Frequency of single shocks in all bootstrapped covariance decompositions which accord to a specific predetermined sign pattern
cov_bs	Covariance matrix of bootstrapped parameter in impact relations matrix
method	Used bootstrap method
VAR	Estimated input VAR object
